Structural and Functional Analysis of the Protein Network Controlling Centriole Biogenesis

Thesis

Structural and functional analysis of the protein network controlling centriole biogenesis

M. Sandra Schneider BSc MSc

This thesis is submitted for the degree of Doctor of Philosophy in

Faculty of Science

Department of Life, Health & Chemical Sciences at

the Open University

June 2016

Acknowledgements

My sincere thanks goes to Professor David M. Glover, who gave me the opportunity to join his research group as research assistant and undertake my PhD research in his laboratory (Cell Cycle Genetics group, Department of Genetics, University of Cambridge, UK). This thesis would not have been possible without his support and kindness, for which I am utmost grateful.

I also greatly thank Dr. Robert Saunders for his everlasting optimism and support over the past years as my supervisor at The Open University. I also thank Dr. Nacho Romero for being my internal supervisor.

A great thank you goes to everyone in David's lab, past and present, for their support, food for thoughts on my research and for an ambitious lab environment. In particular, I would like to thank Dr. Dzhindzhev, Dr. Lipinszki, Dr. Tzolovsky and Miss Chu for their collaborations and discussions.

A special thanks goes to my family, friends and especially Dan for his continuous support and believe in me. Cambridge, you have been great.

Abstract

Centrosomes function as microtubules organising centres in mitosis or as basal bodies in cilia and flagella formation. The duplication of centrioles, which are at the core of each centrosome, is tightly regulated and occurs only once per cell cycle, which allows for correct segregation of chromosomes. In *C. elegans*, only five proteins are essential for centriole duplication. How their *Drosophila* counterparts interact with each other on a molecular level still remains largely unknown.

To further our understanding of the protein interactions governing centriole duplication, I applied *in vivo* and *in vitro* methods to design a protein interaction network at the centriole. I analysed mass spectrometry data from purifications of ProteinA-tagged centriole duplication proteins to identify *in vivo* protein complexes; and performed direct *in vitro* and *in vivo* protein-protein interaction assays.

Additionally, I studied the *Drosophila* proteins Ana2 and Sas6; showing that Plk4 phosphorylates S318, S365, S370, and S373 of the Ana2-STAN motif; which identifies a direct substrate of Plk4. By *in vitro* interaction studies I show that Sas6 aa276-432 and Ana2-STAN interact directly, if the latter is phosphorylated by Plk4. The depletion of Ana2 or expression of Ana2-4A causes loss of centrosomes in *Drosophila* cell culture, which was not observed when expressing Ana2-4D. This supports the importance of Plk4-mediated phosphorylation of Ana2-STAN in centriole duplication.

Mass spectrometry analysis of Sas6 purifications from cultured *Drosophila* cells identified the uncharacterised protein CG33052 (Dragon) and reciprocal purifications of tagged Dragon from *Drosophila* cell culture and syncytial embryos identified Sas6. By *in vitro* interaction studies I confirm that Dragon aa191-318/GoRab and Sas6 aa351-462/HsSas6 interact directly. The deletion mutant DragonΔaa260-286 does not interact with Sas6 *in vitro* or *in vivo*, and fails to rescue centriole duplication after Dragon depletion. Dragon localises to the *trans*-Golgi and co-localises with Sas6 at the centriole throughout the cell cycle.

Table of Contents

List of Figures

List of Tables

List of Abbreviations

AD	Activation Domain
AKAP450	A-kinase anchor proteins, *Drosophila* homologue Plp
AL	Activation Loop
Ana1, 2, 3	anastral spindle 1, 2, 3
Asl	Asterless
BD	Binding Domain
Cdk1	cyclin-dependent kinase 1
CLASPs	cytoplasmic linker-associated proteins
Cnn	centrosomin
CtBP	C-terminal binding protein
D-Plp	Drosophila pericentrin-like protein
DRE	downstream regulatory element
ER	endoplasmic reticulum
GMAP210	Golgi microtubules associated protein of 210kDa
IFT	intraflagellar transport
IM	interaction motif
IVTT	*in vitro* transcription translation
KDEL	Lysine-Aspartic acid-Glutamic acid-Leucine
KLP10A	kinesin-like protein 10A
LC8	dynein light chain
MDM2	mouse double minute gene number 2
MTOC	microtubules organising centre
Nap1	Nucleosome assembly protein 1
PB	polo box
PCM	pericentriolar material
PISA	present in Sas6
Plk	Polo like kinase
Poly-Ub/ pUb	poly-Ubiquitin
PP2A	protein phosphatase 2A

PPH4	protein phosphatase 4
Rcd4	Reduction in Cnn dots 4
RNAi	ribonucleic acid interferance
Sas4, 6	spindle assembly abnormal 4, 6
Spd2	spindle defective 2
STAN	STIL Ana2
TGN	*trans*-Golgi-network
TIM	truncated in microcephaly
Zyg-1	zygote defective-1

Chapter 1

Introduction

1 Introduction

1.1 The cell cycle

The cell cycle is a series of events that are categorised into interphase and mitosis; with interphase being separated into G_1-, S-, G_2- and M-phases (Figure 1-1). During each cell cycle the cell's DNA is replicated in S-phase and the duplicated chromatids are segregated to the opposite poles of the mitotic spindle during M-phase followed by the division of the cell into two identical daughters at cytokinesis.

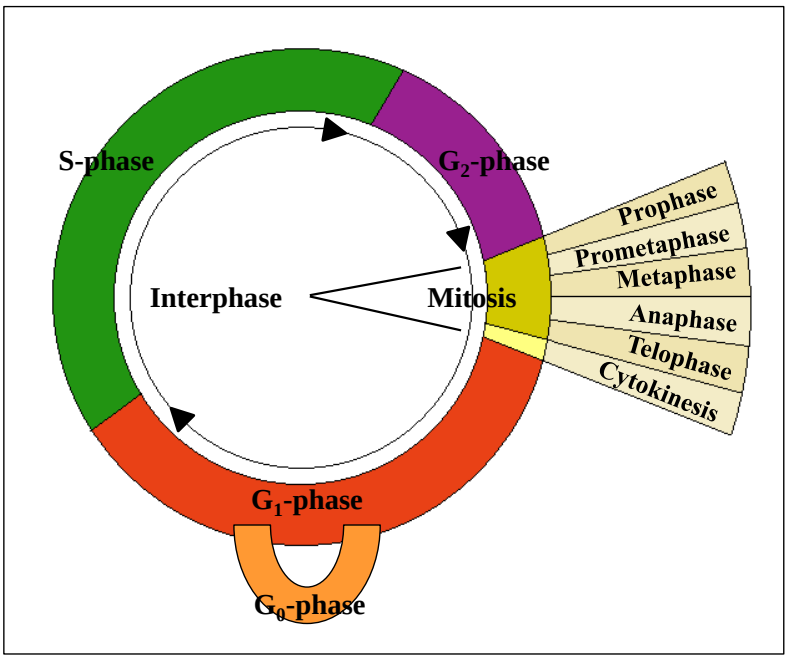

Figure 1-1 Cell cycle phases. The cell division cycle is divided into interphase and mitosis. Interphase composes of G_1-phase where cell growth occurs and centriole duplication begins, S-phase in which the DNA replicates and G_2-phase which is characterised by final cell growth and the completion of centriole duplication. During mitosis the duplicated DNA copies are separated into daughter cells. G_0-phase is a dormancy phase of the cell when conditions do not favour to progress through G_1-phase and into S-phase.

M phase initiates with prophase, when the chromatin fibres condense to chromosomes, followed by the beginning of nuclear envelope breakdown at the end of prophase; and the migration of the two centrosomes to opposite sides of the nucleus. Centrosomes are the major MTOCs (microtubules organising centres) and are also important for mitotic progression as they recruit the mitotic kinases Plk [1] and Aurora A [2]. The minus ends of the microtubules are nucleated from the spindle poles and the plus ends of the microtubules grow towards the chromosomes, which progress to the equator of the cell. The kinetochores at the centromere of each chromosome function as the attachment site for microtubules from each spindle pole, to form bipolar attachments (Figure 1-2). Kinetochores are conserved multiprotein complexes and they support the spindle microtubule anchoring by nucleating short microtubule stubs themselves [3,4]. Only end-on, balanced microtubule attachments stabilise each sister kinetochore to its respective pole. Incorrect attachments are labile and become disattached through the activity of Aurora B [5–9]. At metaphase, all chromosomes align at an equatorial plan and in some species oscillate due to fluctuations in the balance of microtubule tension (Figure 1-2). During anaphase, the sister chromatids are separated by separase protease that cleaves cohesin at the kinetochores (Figure 1-2) [10], and the separated sister chromatids segregate to opposite cell poles as a result of depolymerisation of the plus-ends of microtubules and the acting of minus-end directed motors. A surveillance mechanism, the ‘Spindle Assembly Checkpoint’ (SAC), functions at kinetochores to prevent the separation of any sister chromatids until all kinetochores are attached to microtubules and the chromosomes are perfectly aligned at the metaphase plate [11]. The cell poles move further apart in anaphase B as a result of the sliding of overlapping spindle pole microtubules of opposite polarity. The spindle reorganises in late anaphase and the resulting ‘central spindle’ participates in organising the cleavage furrow that enables cell membranes to form between the telophase nuclei. Cytokinesis divides the cell into two identical daughters.

The interphase that follows mitosis is separated into three events, G_1-phase, S-phase and G_2-phase. Cells can enter an additional state in G_1-phase, the dormancy or G_0-phase, when they do not progress to S-phase due to unfavourable conditions such as limiting growth factors or lack of nutrients. Otherwise, G_1-phase is the main phase of cell growth and the

time at which centrosome duplication begins. Chromosomal DNA is regulated during S-phase, and the subsequent G_2-phase is characterised by final cell growth and the completion of centrosome duplication.

The centrosome comprises of a pair of centrioles (mother and daughter) surrounded by PCM (pericentriolar material). In addition to their mitotic function as MTOCs to organise the formation of the bipolar spindle, the mother centriole at their core can template formation of cilia and flagella.

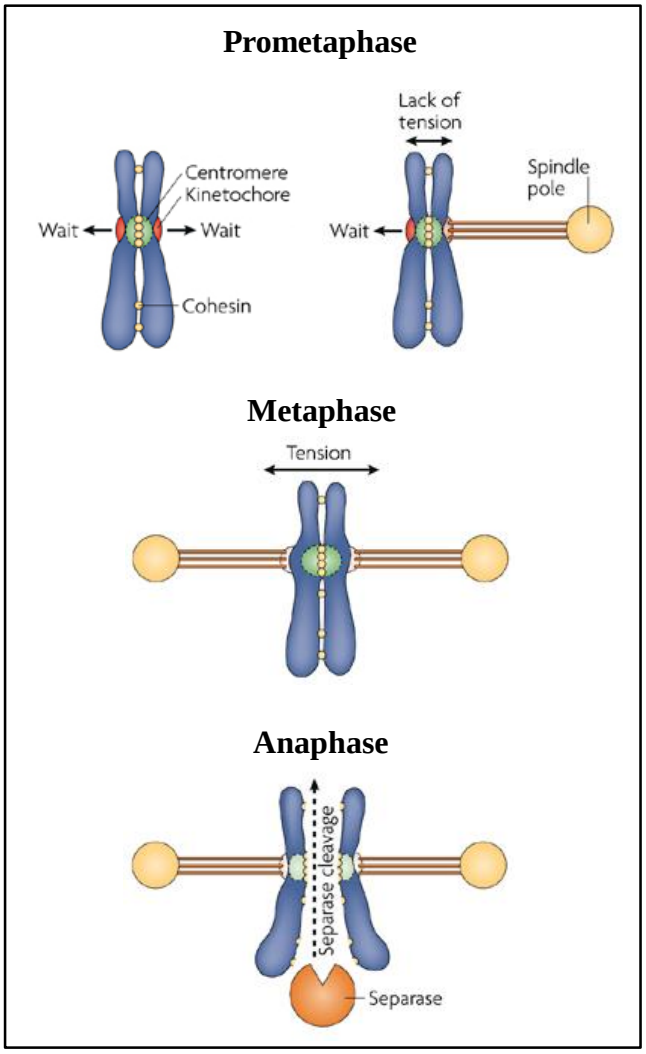

Figure 1-2 Attachment of microtubules to the kinetochores and subsequent sister chromatid separation. In prometaphase the spindle microtubules attach to the kinetochores of the centromeres, leading to bipolar attachment. The chromosomes oscillate, align at the central metaphase plate and the attached spindle microtubules cause tension at the centromere. Activated separase then cleaves the sister chromatids at anaphase and they are pulled to opposite poles. Figure reproduced with modifications and permission from [11].

1.2 The Centrosome and cell cycle

In the late 19th century, Van Beneden and Theodor Boveri described two dots within the spindle poles that Boveri named the centrosome. But only in the mid 20th century did electron microscopy reveal the organisation of centrioles at their core [12,13]. In a little more than a decade, we have begun to understand the assembly and function of centrioles and centrosomes at the molecular level.

Centrioles are present in eukaryotic species which form cilia and flagella but not in higher plants and higher fungi, which do not form these structures. Centrosomes participate in many cellular and developmental processes, including cell polarity, cell motility and cell division. To form a cilium or flagellum, the mother centriole of a centriole pair converts into the basal body at the cell membrane in the G_0 phase of the cell cycle. The basal body then assembles cilia and flagella which function in signal transduction and cell motility. Many diseases are linked to structural, functional and numerical abnormal centrioles, including ciliopathies and cancer.

The duplication cycle of centrioles is generalised in Figure 1-3. This process begins at the G_1- to S-phase transition when one new daughter centriole (procentriole) begins to form orthogonally at the proximal end of each of the two linked mother centrioles; progresses through S-phase and into G_2-phase where the daughter centrioles elongate to their full size. At this point the only physical difference between mother and daughter centrioles are distal and subdistal appendages at the mother centrioles. At entry into mitosis, the linker between the two mother centrioles dissociates, the mother centrioles recruit PCM, and the two centrosomes separate and migrate to opposite sides of the nucleus where they will function as MTOCs. Each centrosome consists of a mother-daughter pair of centrioles with PCM recruited to surround the mother and each centrosome forms one spindle pole of the mitotic spindle. As mitosis progresses, the daughter centriole becomes licensed to recruit PCM in the next cycle. After mitosis, each of the two resulting daughter cells receives one centriole

pair that consist of a mother and daughter centriole that separate but remain connected by a protein linker.

The coupling of centrosome duplication and the cell cycle is a major regulating mechanism. But each can occur independently, for example Aphidicolin blocks α-DNA polymerase and therefore DNA replication but centrosome duplication remains unperturbed in many cell types.

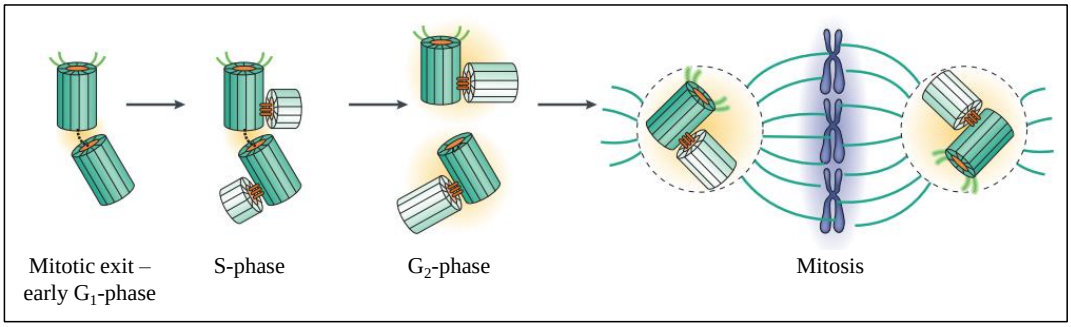

Figure 1-3 Centriole duplication. After mitotic exit two centrioles are loosely linked by a protein linker. At the G_1/S-phase transition, each of the centrioles functions as a mother centriole and procentriole formation is initiated at their proximal ends. The daughter centriole assembly continues throughout S-phase until it reaches its full length in G_2-phase. The mother centriole then recruits pericentriolar material and the two centrosomes separate by the removal of the protein linker. Each of the centrosomes then migrates to opposite sites of the nucleus where they function as MTOCs and generate the mitotic spindle. Figure reproduced with modifications and permission from [14].

1.3 Centriole structure and cartwheel

The process of centriole duplication is tightly regulated and linked to cell cycle progression to guarantee correct centriole numbers. The initial step in centriole duplication is the formation of the procentriole at one single site on the proximal end of the mother centriole. The hierarchy of protein recruitment to form the daughter centriole was first described in *C. elegans* and extensive RNA interference (RNAi) and genetic screens identified five proteins

as essential for centriole duplication; Spd2 (spindle defective 2), the Serine/Threonine kinase Zyg-1 (zygotic defective: embryonic lethal 1), Sas6 (spindle assembly abnormal 6), Sas5 and Sas4 (spindle assembly abnormal 5 and 4 respectively) [15–23]. Table 1-1 shows the homologues of *C. elegans* in *Drosophila* and *Homo sapiens*. Their sequential recruitment was analysed by electron tomography of staged *C. elegans* one-cell embryos. This revealed firstly, the formation and elongation of a central tube and secondly, the assembly of nine singlet microtubules during daughter centriole formation. The pathway of centriole formation is believed to be conserved between species and in *C. elegans* it requires the coiled-coil protein Spd2 to recruit the protein kinase Zyg-1, followed by recruitment of the Sas6-Sas5-protein-complex as prerequisite for procentriole assembly, and Sas4 recruitment for microtubules assemble onto the central tube.

In this section I will discuss what we know of the structure of these proteins or their orthologues in *C. elegans* and other organisms. I will return to what we know of their role in centriole duplication in section 1.4.

Table 1-1 Homologues of centriole duplication proteins of *C. elegans*, *Drosophila* and *Homo sapiens*.

Homologues		
C. elegans	*Drosophila*	*Homo sapiens*
Spd2	-	Cep192
Zyg-1	Plk4	Plk4
-	Asterless	Cep152
Sas6	Sas6	Sas6
Sas5	Ana2	STIL
Sas4	Sas4	CPAP
-	Bld10	Cep135

The microscopy techniques, especially in the area of super-resolution, have advanced in the recent years, and in *Drosophila*, it is now possible to view the centriole as a cylinder which

can be differentiated into five different regions and into which different centriole duplication proteins have been localised (Figure 1-4) [24–30].

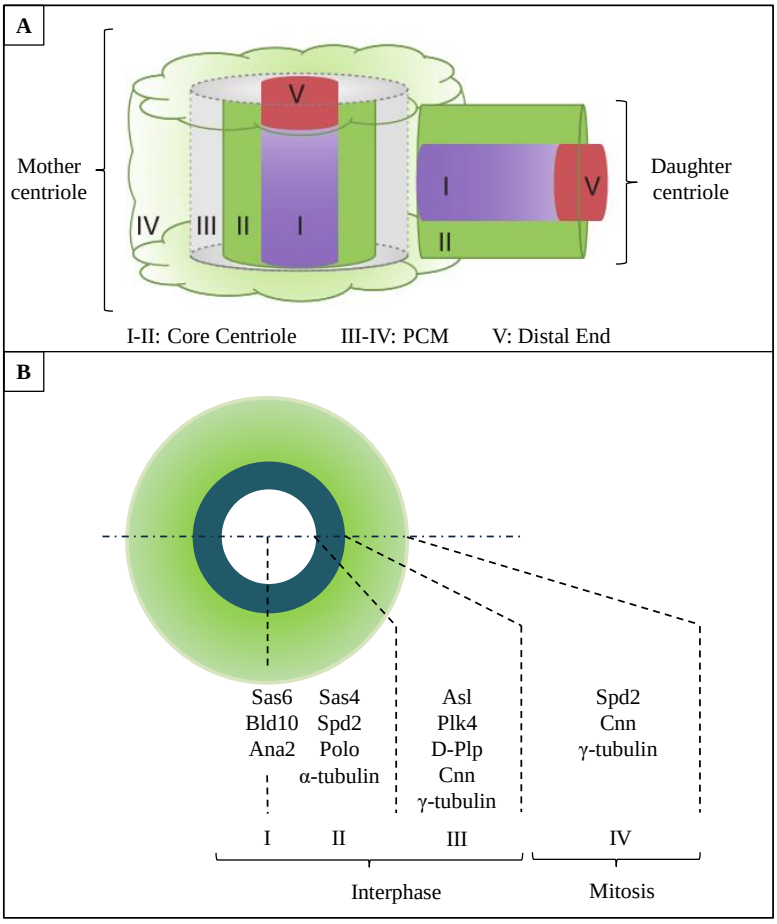

Figure 1-4 The division of *Drosophila* centrosome into five zones. (A) The schemata shows the mother and daughter centriole and PCM. Zones I-II represent the core centriole; zone III-IV represent the PCM and zone V represents the distal end. Figure reproduced with modifications and permission from [24]. (B) Schematic proximal view of a centriole; indicating the localisation of the named proteins at each zone during interphase and mitosis.

Centrioles are characterised by a precise 9-fold symmetry evident in the central cartwheel and in the organisation of its microtubules [31–33]. The cartwheel is believed to represent a conserved building mechanism. The cartwheel appears first during procentriole formation at the proximal end of the centriole. It consists of an inner hub from which nine spokes radiate

outwards, which then each connect to an A-microtubule (Figure 1-5). These microtubules are stable due to tubulin modifications (e.g. tubulin glutamylation) [34] and comprise of triplets in most species but in *Drosophila* and *C. elegans*, duplets or singlets respectively predominate. Each A-microtubule is comprised of 13 α- and β-tubulin-containing protofilaments, followed by anti-clockwise assembly of the B- and C-microtubules of which each comprises 10 α- and β-tubulin-containing protofilaments [35–37]. Each of the partial microtubules forms a complete tubule by sharing 3 protofilaments with the preceding microtubule and each A-microtubule links with the neighbouring spoke's microtubule, to form the outer cylindrical ring of the centriole. The centriole microtubules show polarity, with the minus ends located at the proximal end of the centriole, which coincides with the site of cartwheel assembly. Sas4 protein is necessary for polymerisation of centriolar microtubules and it localises to the microtubules wall [24]. Overexpression of the human homologue of Sas4, CPAP, causes centriole elongation [38–40]; Sas4/CPAP also interacts with STIL and Cep135 [41–44] but the function of these interactions are still unknown. Additionally, γ-tubulin is necessary for the assembly of microtubules. It is part of the γ-tubulin ring complex and localises to the minus end microtubules of the A-microtubules [45–49].

Mother centrioles carry appendages at their distal end (Figure 1-5 B and C). The subdistal appendages function in anchoring of the minus ends of the cytoplasmic microtubules to organise radial arrays of microtubules. And the distal appendages function in anchoring the basal body to the cell membrane during ciliogenesis. Once the daughter centriole has passed through mitosis it will mature into a mother centriole and also carry these appendages [50].

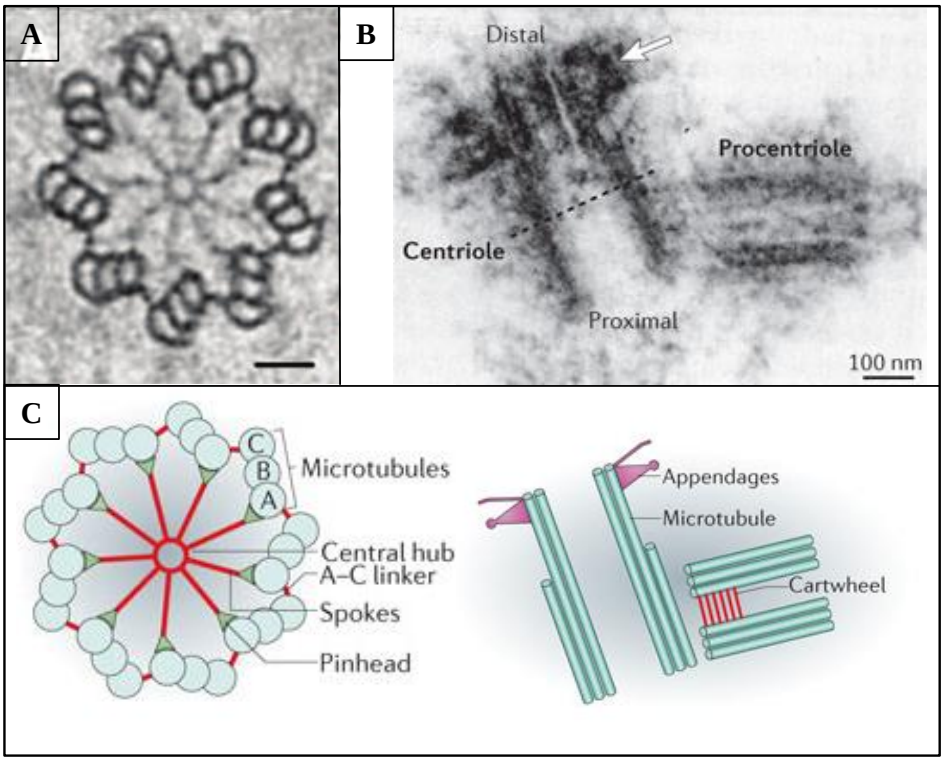

Figure 1-5 Centriole and cartwheel structure. (A) Ultrastructure of a cross-section of the proximal end of a *Trichonympha* reveals the cartwheel. At the central hub there are nine radiating spokes, which join the microtubules triplets. (B) Ultrastructure of a human centriole and procentriole; arrow indicates the distal and subdistal appendages next to the mother centriole. (C) Schemata of A and B. Additionally indicating the pinhead structures connecting the cartwheel spokes with the A-microtubules, which are in turn connected to the B-microtubules, and to the C-microtubules (left); the A-C-microtubules-linker (left); and the stack of cartwheels (right). Figures reproduced with modifications and permission; (A) from [51]; (B) and (C) from [52].

During procentriole formation, stacks of cartwheel form in the proximal part of the centriole, which vary in size between species, e.g. in *Drosophila* sperm, basal bodies are 2.5µm long whereas *C. elegans* centrioles are 150nm [53]. Mammalian centrioles lose their cartwheels during mitosis [37,54,55]. The *Trichonympha* centriole on the other hand is formed of many hundred cartwheels in approximately 90% of its centriole length [56]. This proves ideal for structural studies by cryo-electron tomography [36,51]. These reveal that neighbouring spokes of the cartwheel layers merge 20nm from the hub and end in a pinhead structure, which consist of the pinbody and two pinfeet that connect it to the A-microtubules (Figure 1-6) [36].

The vertical distance between the merged spokes is 17nm, that correlates with the size of two tubulin dimers.

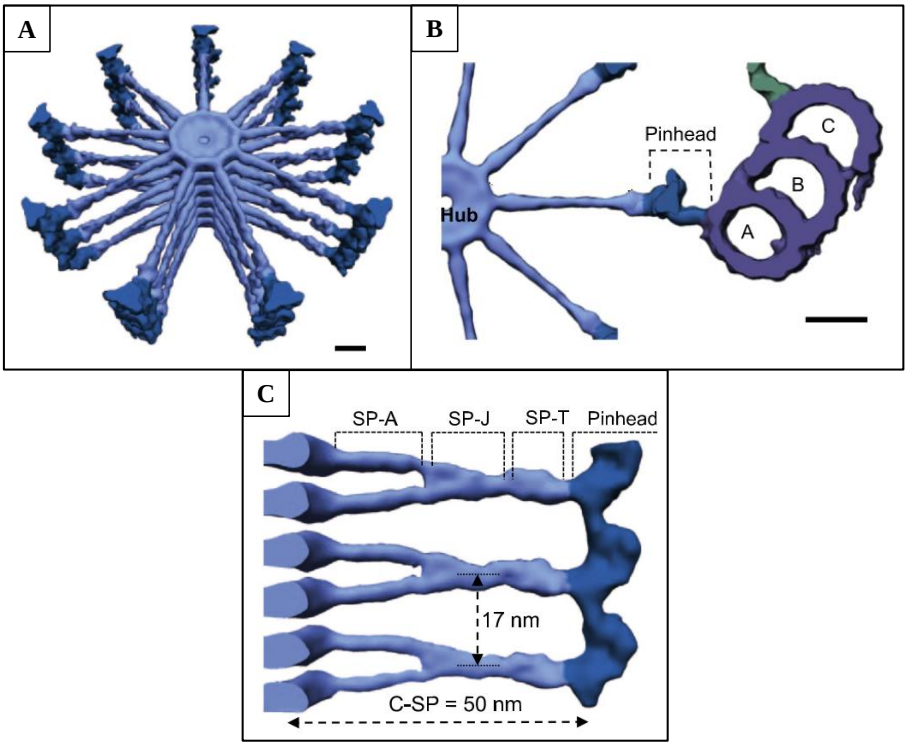

Figure 1-6 Characteristics of the proximal centriole region and cartwheel stack. (A) 3D representation of *Trichonympha* cartwheel stack showing the individual layers which show the central hub and nine radiating spokes each, which end in the pinhead structure. (B) 3D representation of the *Chlamydomonas* cartwheel-pinhead-microtubules triplet. (C) Longitudinal section of the cartwheel spokes (C-SP), which comprise of the spoke arm (SP-A), the spoke junction (SP-J), and the spoke tip (SP-T); connecting to the pinhead (partially indicated). Figure reproduced with modifications and permission from [36].

Despite the structural knowledge of the cartwheel and the microtubules the basis for the 9-fold symmetry is still unknown. In most organisms, the cartwheel appears before microtubule assembly [57–60] but *C. elegans* centrioles adopt 9-fold symmetry in the absence of any cartwheel structure [53]. Moreover, in *Paramecium*, the circular microtubules become arranged before cartwheel formation in basal bodies [61]. That the cartwheel contributes to the 9-fold structure has been demonstrated by multiple mutants that show structural defects. Also a

Chlamydomonas null-mutant in Bld10p, which encodes a Sas6-interacting protein, lacks centriolar microtubules [62] and a truncated Bld10p mutant leads to cartwheels with nine shorter spokes that recruit only eight microtubules due to reduced circumference based on shorter cartwheel spokes [62,63]. On the other hand, depletion of its respective homologue in *Drosophila* and human, Bld10 and Cep135 respectively, still permits centriole formation but they appear unstable [32,64–66]. This suggests that Bld10p/Bld10/Cep135 localis to the distal part of the cartwheel spokes and might function in extending the cartwheel to its full length and/or in stabilising the connection between cartwheel and microtubules [65,67]. This is supported by the observations that Bld10p/Cep135's N-terminus interacts with microtubules in human cells [43,68]; and that Bld10p/Cep135 C-terminus interacts with the cartwheel protein Sas6 [43,63].

Additionally the cartwheel protein Sas6 is required for the 9-fold symmetry of centrioles in zebrafish, human cells, *Drosophila*, *C. elegans* and *C. reinhardtii* [63,69–71]. A null-mutant of the homologue bld12 in *Chlamydomonas* causes loss of the central hub and cartwheel spokes [70]; and a mutant leads to 20% of cells with circular centrioles of which 30% have abnormal numbers of microtubules ranging between seven to 11 triplets [71]. Similar findings were made in *Drosophila*. Thus, bld10p/Bld10/Cep135 and bld12/Sas6 all contribute to the 9-fold symmetry of the centriole [54,72,73].

Structurally, Sas6 is characterised by a N-terminal head domain with a PISA motif (present in Sas6; region of homology), a coiled-coil domain and a small, poorly conserved and unstructured C-terminal domain [72]. The protein forms parallel homodimers via its coiled-coil domains, which exhibit a coiled-coil rod with two N-terminal globular domains, with the latter being positioned next to each other but in mirror image position (Figure 1-8). Each N-terminal head of the dimer weakly interacts via hydrophobic bonds with an N-terminal head of another Sas6 dimer, leading to the assembly of nine Sas6 dimers to the inner hub/ring like structure with the nine homodimerised coiled-coil domains of the protein radiating out (Figure 1-8). Its structure has been elucidated for *C. elegans*, *C. reinhardtii*, *Chlamydomonas* and zebrafish using X-ray crystallography, analytical gel-filtration, and *in silico* structural modelling [63,69,74,75]. In solution, Sas6 molecules are able to oligomerise and form ring like

structures similar to the cartwheel hub [63,69]. This gives important insight into the nature of the 9-fold symmetry of centrioles. It predicts a 42° angle between the homodimers and a ring of 23nm diameter, which is close to the expected 40° angle from a 9-fold radially symmetry cartwheel and the observed 20-25nm diameter observed for the central hub by electron microscopy [60,69,76], with the model for Sas6 *C. reinhardtii* in Figure 1-7. On the other hand, *C. elegans* exhibits a tube like structure rather than a cartwheel [53] and X-ray crystallography shows that its Sas6 dimerise to a right-handed helical filament with 9-fold radial symmetry, leading to the tube rather than cartwheel formation (Figure 1-9) [77,78]. Just like the cartwheel, the tube can function as a scaffold for microtubule assembly. It was also suggested that two Sas6-spirals might be intertwined to form the central tube in *C. elegans* (Figure 1-9 C and D) [78]. The ability of Sas6 to self-assemble might explain why some centrioles can form *de novo*. But it also suggests there must be a tightly regulated process for Sas6 oligomerisation to prevent spontaneous cartwheel assembly. Therefore, Sas6 is the likely candidate to establish the universal 9-fold symmetry of centrioles.

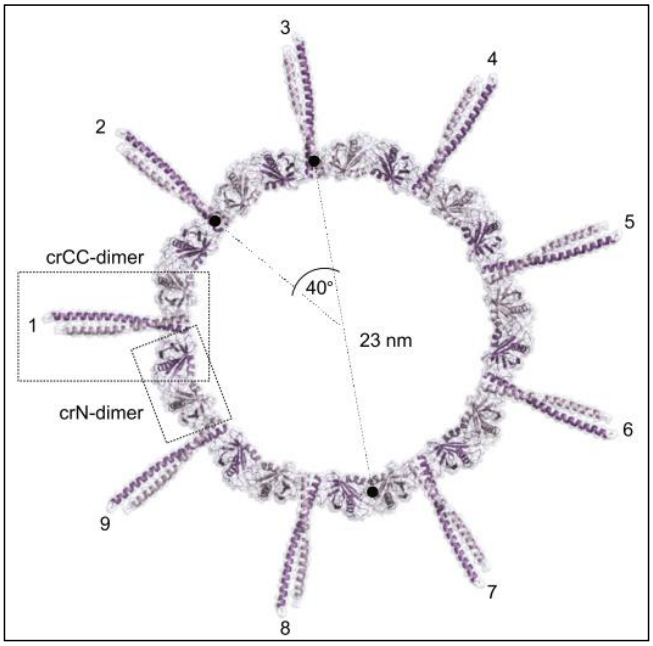

Figure 1-7 Bld12p (Sas6 homologue) oligomer model of *C. reinhardtii*. Organisation of nine coiled-coil homodimers according to their interacting N-terminal domains leads to a 9-fold symmetric cartwheel ring, exhibiting a diameter of 23nm, with nine radiating spokes. Figure reproduced with modifications from [69].

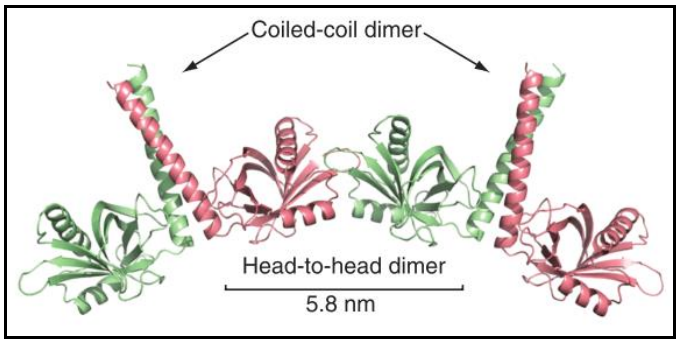

Figure 1-8 3D model of a Sas6 ring assembly. Sas6 dimers form by homodimerisation of their coiled-coil domains. Nine homodimers interact weakly via their N-terminal head domains and form the 9-fold symmetry of the centriolar cartwheel. Figure reproduced with modifications and permission from [63].

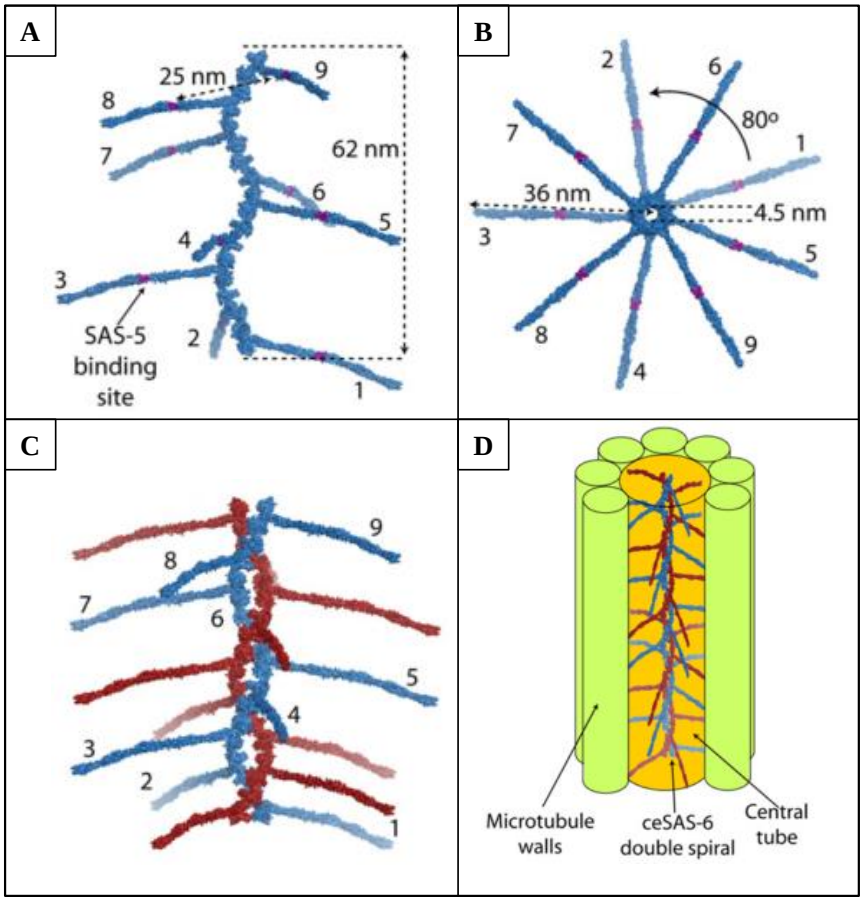

Figure 1-9 Sas6 forms a spiral in *C. elegans* which provides the basis for the 9-fold symmetry of the centriole. (A and B) Model of a single Sas6 spiral with nine homodimers (numbered, orthogonally viewed). (C) Model of two Sas6 spirals intertwined. (D) Centrosomal model of *C. elegans* containing the Sas6 double spiral, of which four turns account for the central tube. Original figure reproduced from [78].

Zone 5 of the centriole was described as a distal ‘cap’ to which the centriolar proteins CP110 and Cep97 localise and function in the regulation of centriole length [39,79,80]. The two proteins are co-ordinately recruited with Cep97 being required to stabilise CP110 at the centriole [81]. The loss or depletion of CP110 from human cell culture leads to elongated centriole microtubules [39]. In contrast, the depletion of CP110 in *Drosophila* cells leads to shortened centriolar microtubule apparently as a result of the ‘exposure’ of the centriole to Klp10A, a depolymerizing kinesin-like protein [82].

1.4 Centriole duplication and its proteins Plk4, Sas6 and Ana2

1.4.1 Plk4

Plk4 is the conserved master kinase of centriole duplication [73,83–85]. Its counterpart in *C. elegans* is Zyg-1 which, although more divergent, has the distinct domains of all other Plk4 kinases [86]. *Drosophila* Plk4 is structurally similar to other members of the polo-like kinase family but there are some significant differences; all Plks carry an N-terminal catalytic domain but Plk4’s C-terminal part contains three Polo box (PB) motifs compared to the two PBs in other family members (Figure 1-10) [87]. The polo-box motifs function to direct protein interactions, intracellular targeting, substrate binding, dimerization and auto-inhibition of kinase activity [1,86,88–90].

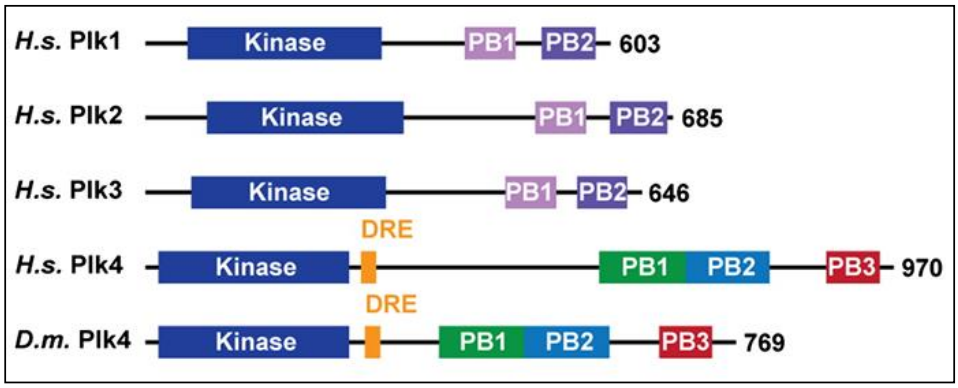

Figure 1-10 Polo-like kinase family and their domains of *Homo sapiens* and *Drosophila*. All kinases contain an N-terminal kinase domain. Plk1-3 contain two Polo box domains. But Plk4 is characterised by three polo boxes (PB) of which PB1 and PB2 function as a cryptic polo box. After homodimer-dependent autophosphorylation of Plk4, $SCF^{Slimb/\beta TrCP}$ ubiquitin ligase recognises the phosphodegron 'downstream regulatory element' (DRE), leading to degradation (see Figure 1-11). Figure reproduced with modifications and permission from [87].

The localisation of Zyg-1/Plk4 to the site of centriole duplication requires Spd2 in *C. elegans* [53,91], Asterless in *Drosophila* [92] and the homologues of both proteins, Cep192 and Cep152 respectively, in mammalian cells [93,94]. Plk4 localises around the whole circumference of zone 3 of the centriole in G1 but becomes focused at a single site at the initiation of duplication [95]. This cannot be explained by its interaction with Cep192/Spd2 and Cep152/Asterless, as both localise around the entire centriole following the completion of centriole to centrosome conversion. How Plk4 becomes localised at a single site is not clear. The important role of Plk4 in centriole duplication is reflected by loss of centrioles after depletion of Plk4, and by the over-amplification of centrioles in many cell types and species when Plk4 is overexpressed [73,83–85,96,97]. Overexpression can also lead to *de novo* centriole formation in *Drosophila* eggs which lose their centrioles during oogenesis [20]. When Plk4 is overexpressed, multiple sites of centriole duplication are observed on the mother centriole to form a 'centriole rosette' [73,84]. Both, upregulation and downregulation of Plk4 have been associated with tumorigenesis [99–101].

The regulation of Plk4's activity for centriole duplication requires transcriptional control, localisation, regulated degradation and auto-inhibition of the kinase activity (Figure 1-11) [1,90,102–106]. A major mode of regulation of Plk4 appears to be through autoinhibition, achieved through homodimerisation of polo-box 1 and polo-box 2 (cryptic polo box; Figure 1-11 A and B) [87]. Homodimerisation itself or the recruitment of an unknown binding partner of PB3 to move the linker 1 (L1) away from the kinase's activation loop allows for auto-phosphorylation of a phosphodegron [104,107–109] (Figure 1-11C). This permitts for binding of the ubiquitin ligase complex $SCF^{Slimb/\beta TrCP}$ [103–105,107,110,111] (Figure 1-11D) and initiates Plk4 self-destruction by targeting it to the proteasome (Figure 1-11E) [103,105,108,109,112]. Although we have this outline of this aspect of Plk4 regulation, we still have much more to learn to fully understand how it controls centriole duplication.

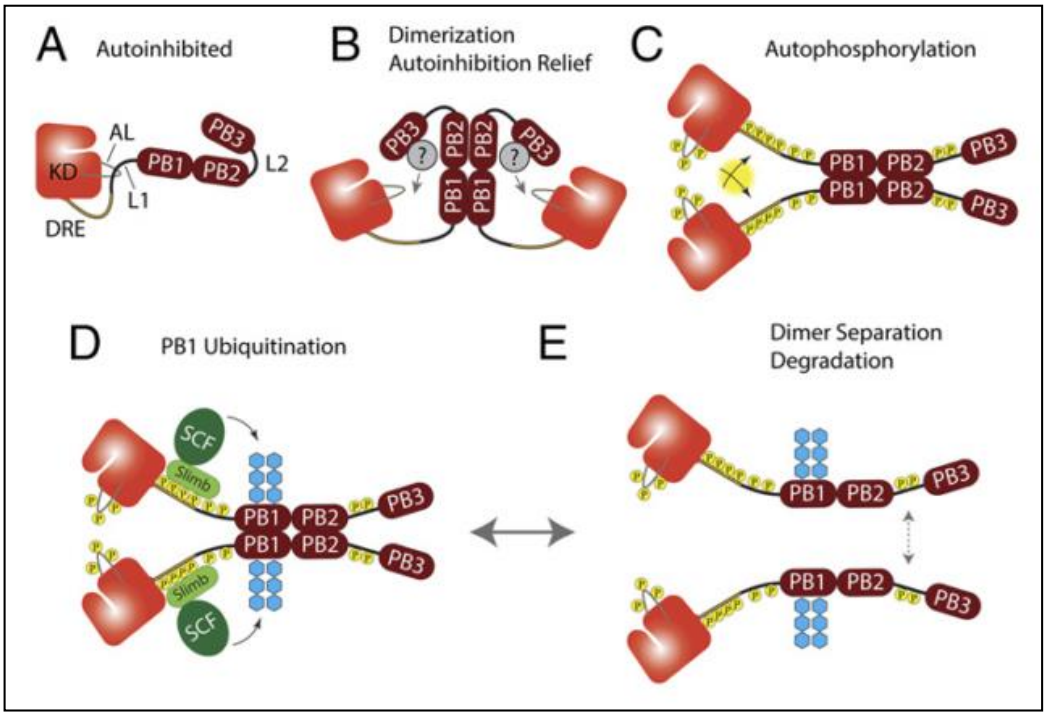

Figure 1-11 Speculative model for activation and regulation of Plk4. (A) Plk4 is autoinhibited by a link of Linker 1 (L1) and Activation loop (AL), which allows for homodimerisation by Polo Box 1 and 2 (PB1, PB2). (B) In the homodimerised stage, a binding partner of PB3 moves L1 away from AL which leads to autoinhibition relief. (C) This allows for autophosphorylation of Plk4. (D) Followed by $SCF^{Slimb/\beta TrCP}$ recruitment and ubiquitination of PB1. (E) And separation of the dimers. Original figure reproduced from [106].

1.4.2 Sas6

The recruitment of Sas6 to the procentriole in human cells is independent of Plk4. However its maintenance at the procentriole depends upon Plk4. This is similar to the relationship between Sas6 and Zyg-1 in *C. elegans,* where recruitment of Sas6 is directly regulated by Zyg-1 but is independent of Zyg-1 kinase activity [15,91], whereas the Zyg-1-phosphorylation of Sas6 at Ser123 is suggested for Sas6 maintenance [54,113]. However, this residue is not conserved in other species. Also, the recruitment hierarchy of human Sas6 and CPAP corresponds to that of Sas6 and Sas4 in *C. elegans*; HsSas6 depletion prevents the recruitment of CPAP whereas HsSas6 is still recruited after CPAP depletion, suggesting Sas6 is recruited upstream of CPAP/Sas4. Some species-specific differences are also seen from overexpression experiments. Overexpression of non-degradable HsSas6 causes amplification of centrioles whereas overexpression of DmSas6 in syncytial embryos leads to *de novo* formation of MTOCs that lack centrioles at their core [71]. However, when *Drosophila* Sas6 and Ana2 are co-expressed, they assemble into extended tubes that interact with proximal ends of centrioles and bear structural resemblance to the inner cartwheel of centrioles, when also co-overexpressed with Plk4 [114]. This suggests, that *Drosophila* Sas6 and Ana2 together drive cartwheel formation of centrioles, in a Plk4 dependent manner.

It is of great interest to know how the basic ring of Sas6 homodimers is stabilized to promote formation of a mature centriole. Two mechanisms have been proposed for regulating HsSas6 protein levels. First, that Sas6 is targeted for degradation by APC/C^{Cdh1} through its C-terminal KEN-box [54,115]. This keeps Sas6 levels low and could limit the number of procentrioles per mother centriole to one. Second, that SCF targets Sas6 for degradation by ubiquitination via Fbxw5 (Fbox protein) [115]. Fbxw5 on the other hand is regulated by degradation by the APC/C in mitosis before it accumulates at G_1/S-phase. Plk4 phosphorylates Fbxw5 which then suppresses the ubiquitination and consequently full degradation of Sas6 in S-phase [115]. This linkage would guarantee a timely increase and decrease of Sas6 protein levels to control centriole assembly. But there is still little structural

information on how the mother centriole recruits Sas6 to a single site of procentriole formation and how the nascent cartwheel and centriole are linked to the mother centriole.

1.4.3 Ana2

It has been suggested that *Drosophila* Ana2 and human STIL are homologues of *C. elegans* Sas5, despite their limited sequence homology. Significantly, there is an approximately 20aa coiled-coil domain in the central part of each protein together with a conserved STAN motif in the C-terminus. The STAN motif is a region off approximately 90aa that exhibits 31% sequence identity between Ana2 and STIL and is even more distantly related to Sas5 [116]. Finally there is a conserved TIM (truncated in microcephaly) motif at the very C-termial end of Ana2, STIL and Sas5 that has been identified [117]. In human cells, STIL exhibits an asymmetric localisation to the daughter centriole and is essential for procentriole formation. In cultured human cells Sas6 is thought essential for STIL recruitment [41,117]. However there it is uncertain whether reciprocally STIL supports the recruitment of HsSas6 to centrioles [41,117,118]. This is in contrast to *C. elegans*, where Sas5 and Sas6 protein localisation is co-dependent [72]. Additionally, when Sas6 and/or Sas5/Ana2/STIL are overexpressed, it leads to over-amplification of centrioles, which is similar to Plk4 overexpression, which causes over-amplification and *de novo* formation (in unfertilized eggs) of centrioles [41,54,72,117–119]. In *Drosophila* spermatocytes, co-overexpression of Sas6 and Ana2 leads to the assembly of cartwheel-like structures [114]. Recently, it was suggested that the Ana2-Sas6 complex could function as the so far poorly understood linker between the procentriole and mother centriole, which retains the linkage between the two centrioles until their disengagement late in cell division [114]. STIL is recruited to the proximal end of the mother centriole after the G_1-S phase transition, where its signal increases gradually and reaches its maximum at the poles of pro- and prometaphase cells. This is followed by degrease in intensity from the metaphase-to-anaphase transition onwards until it appears absent in late anaphase and telophase cells [117]. A similar path of regulation to the one described above for Sas6 is claimed for STIL. The $APC/C^{Cdc20–Cdh1}$ brings about dependent proteasomal degradation of

STIL after the metaphase-anaphase transition, with Cdc20 being the major APC/C adaptor and the C-terminal Ana2 KEN box being recognised by APC/C at the end of mitosis [117]. Interestingly, the KEN box was observed to be lost in MCPH mutants of STIL, leading to accumulation of STIL protein in the cytoplasm and resulting in centriole amplification rather than interference with STIL function [120]. The degradation of STIL is initiated by its re-localisation from the centriole to the cytoplasm at nuclear envelope breakdown, dependent on Cdk1 (cyclin-dependent kinase 1) [117,120]. The mother and daughter centriole linkage also provides a physical input for regulating STIL levels, whereas their disengagement at the end of mitosis licenses them for reduplication in the next cell cycle [121,122]. It was shown that over-expressed STIL localises as a ring around the proximal end of the mother centriole and causes the near-simultaneous formation of multiple daughter centrioles, which co-localise with Sas6 [117]. This observation supports the theory that STIL and Sas6 function together in centriole duplication in human cells, just as do Sas5 and Sas6 in *C. elegans*. Therefore, it was the more surprising that it has not been possible to detect stable STIL-Sas6-complexes. On the other hand, depletion of STIL by siRNA has a negative effect and suppresses centriole duplication [41,117] but it did not affect the localisation of Plk4 nor Cep152 to the centrioles. By contrast, Plk4 depletion disrupts STIL localisation to the centriole [41]. This suggests that STIL is recruited to the daughter centriole downstream of Cep152 and Plk4. Indeed, STIL recruitment to the centriole was shown to depend on the interaction of its central coiled-coil domain with Plk4 [95,123]. Structurally, it has been shown that Ana2 and Sas6 both form homo-oligomers, and that the central coiled-coil domain of Ana2 is necessary to form a tetramer with an unusual parallel-coil topology, which occurs also but more weakly with STIL [124]. An Ana2 mutant that cannot tetramerise *in vitro* lacks ability for efficient centriole duplication *in vivo* but still allows for the formation of some centrosome like structures which can concentrate at spindle poles [124]. Controversially, an Ana2 tetramer was also observed but requiring dynein light chain (LC8) [125]. This led to the suggestion that the previously mentioned central coiled-coil domain of Ana2 might lead to the Ana2 tetramer formation and that the Ana2-LC8 interaction might rather be important for spindle orientation. Our knowledge of Ana2, its precise role in centriole duplication, and its interaction with other centriole duplication proteins is still very limited and requires further study.

1.5 Centriole maturation and PCM recruitment

The process of daughter centriole assembly to the mother centriole is followed by maturation of the centriole to centrosome conversion for which the mother centriole recruits PCM material. The PCM serves multiple functions: it is the site of microtubule nucleation from tubulin subunits [126], it organises the formation and anchors the mitotic spindle, and it is important for the accumulation of cell cycle regulators [14]. In the past it was believed that the PCM is an amorphous unstructured cloud of proteins surrounding the centriole but more advanced microscopy techniques in recent years, especially super-resolution microscopy, has started to elucidate that the PCM is a highly ordered layer system with hierarchical protein recruitment [24,26,28,127,128]. Many proteins of the PCM have been identified from purified centrosomes and RNAi and localisation screens in *C. elegans* [129], *Drosophila* [130,131] and human cells [132,133]. The molecular interactions of PCM components with each other begin to be uncovered but further study is necessary to understand their complex interacting network at the centriole, how the PCM is regulated and how it functions.

Asterless, which localises to zone III of the centriole, was suggested as a PCM recruiting protein[134], as it links the centriole with the PCM by direct interaction with Sas4 (zone II) [92] and as it is necessary for Cnn recruitment (zone IV) [135,136]. Sas4 also has PCM functions, as Sas4 null-mutant flies show reduced levels of PCM in testes [137,138]. But how the PCM expands to zone IV of the centrosome is still unknown. A possible regulator is Polo kinase whose inhibition prevents γ-tubulin assembly, phosphorylation of Cnn and Pericentrin (zone IV) and PCM expansion [131,139–141]. Additionally, Plk1 maintains the PCM at the centrosome throughout mitosis [142]. Aurora A, which assembles microtubule-nucleating complexes and proteins such as γ-tubulin [143,144], activates Plk1 in conjunction with Bora [145,146].

How the PCM and its proteins are dissociated from the centrosome after mitosis is not fully known. It is suggested that dephosphorylation plays an important part. Inhibition of Polo kinase activity leads to the removal of Pericentrin and γ-tubulin in human centrosomes [142]. Candidate phosphatases that might mediate this are protein phosphatase 4 (PPH4)[147–149]

and/or protein phosphatase 2A (PP2A) [150,151]. Alternatively, PCM proteins could be removed from the centrioles by 'flaring', which is observed in telophase and interphase of *C. elegans* and *Drosophila* embryos [137,152–154].

1.6 Centriole disengagement

Once the cell has gone through mitosis and the mitotic spindle and the centrosomal PCM are disassembled, the two centrioles disengage by loosening their orthogonal connection but they remain connected by a linker. How this process is regulated still remains unknown but it licences the daughter centriole for duplication in the next cell cycle [122,155]. It is suggested that Plk1 and separase regulate the disengagement [156]. Plk1 is suggested to activate separase which in turn loosens cohesion at the centrioles and leads to disengagement [122,156–160]. Supporting this suggestion is the finding that overexpression of Plk1 leads to centriole disengagement in G_2-phase. Cohesion cleavage by Plk1 dependent separase activity also occurs earlier during the metaphase to anaphase transition at the sister chromatids. However a mechanism that would regulate dissociation of two different targets at two different time points has not been found [157,161–164]. Pericentrin has been suggested to be the separase substrate permitting disengagement as it gets cleaved at the meta-/anaphase transition but remains at the centrosome until anaphase [165].

After disengagement, the two centrioles remain linked and both function as mothers in the following cell cycle when new daughter centrioles are assembled. The details about the linker are still emerging but dependency studies suggest that C-Nap1 (Nucleosome assembly protein 1) localises and functions as a docking site for rootletin connecting the two centrioles at their proximal ends [166–169]. Bld10 is a candidate for the connection between the linker and the centriole [170]. The eventual separation of the two centrioles at the G_2/M-phase transition is proposed to be triggered by Nek2 phosphorylation of C-Nap1 and rootletin because overexpression of Nek2 leads spontaneous separation of the centrioles and decreased Nek2 levels inhibit separation [167,168,171–174]. Additionally, the motor protein Eg5

might support the linker separation by forcefully pulling the centrosomes apart before it separates them spatially [175].

1.7 The Golgi, GoRab and cilia signalling pathways

Both the centrosome and the Golgi apparatus have microtubule nucleation abilities [176,177]. At the centrosome, microtubule nucleation and anchoring occurs in the PCM and relies on γ-tubulin complexes [178]. Similar multiprotein complexes are also necessary for microtubule nucleation at the *cis*-Golgi. A well organised microtubule cytoskeleton is important for the organisation of the cell and the regulation of cellular processes. In general, the Golgi apparatus of the cell functions in organising secretory pathways, but interestingly, its structure varies depending on the organism (Figure 1-12). In yeast, the Golgi apparatus consists of dispersed cisterns [179]; in green algae, it consists of parallel aligned stacks of cisterns [180]; in fungi, plants and *Drosophila* multiple Golgi stacks are individually scattered in the cytoplasm but always linked to an individual ER exit site [181–183]; and in mammalian cells multiple Golgi stacks are laterally connected to form a ribbon-like structure [184,185], that localises near the centrosome and the nucleus in a manner dependent on centrosomal microtubules [186,187] and dynein [188]. In mammalian cells, the Golgi apparatus undergoes fragmentation in late G_2-phase, and this appears to be necessary for Golgi inheritance and mitotic entry [189,190]. The protein GMAP210 (Golgi microtubules associated protein of 210kDa) has been suggested to anchor the Golgi to the centrosome [191,192]. In *C. elegans*, GMAP210 functions in Golgi organisation and regulation of cilium length [193], reflecting its role as a receptor of the intraflagellar transport protein IFT20 (see also below). It is suggested that GMAP210 and IFT20 function together in the sorting or transport of cargo destined for cilia in mammalian cells [194]. Microtubules originate directly from the Golgi membrane [195] and their nucleation is dependent on PCM and the *cis*-Golgi protein AKAP450 (A-kinase anchor proteins, *Drosophila* homologue Plp), that in turn is recruited by the *cis*-Golgi protein GM130 [196], the *trans*-Golgi CLASPs (cytoplasmic linker-associated proteins) [177], and additional proteins in a multiprotein complex [197,198]. Whereas the precise role of AKAP450 in nucleating

microtubules at the Golgi is not understood yet, such microtubules formation is independent of the centrosome [177] and might serve to link and fuse Golgi stacks [199,200]. Coordinated function of the centrosome, Golgi and Golgi microtubules are required in cell polarity and migration [186,196,201].

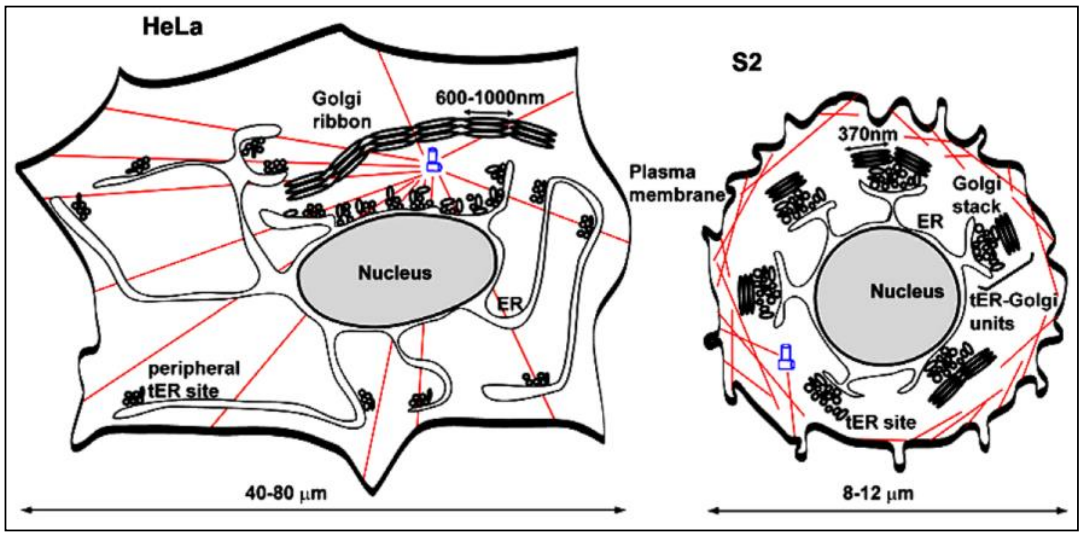

Figure 1-12 Golgi apparatus forms Golgi stacks in *Drosophila* S2 cells and Golgi ribbon in mammalian HeLa cells. The function of the Golgi apparatus for secretory pathways is conserved but it exhibits structural differences. In fungi, plant and *Drosophila*, Golgi stacks are dispersed in the cell but always linked to an ER exit site (example: *Drosophila* S2 cells). The mammalian Golgi apparatus consists of Golgi stacks that are laterally connected and form the Golgi ribbon. At late G_2-phase, the Golgi ribbon gets fractioned into Golgi stacks, which then disassemble for mitosis. Figure reproduced with modifications and permission from [183].

In this study I will focus on the uncharacterised Golgi protein CG33052, which is named Dragon from here onwards. GoRab, also known as SCYL1BP1 (Scyl1 binding partner), is the human counterpart of Dragon and it is highly expressed in skin and osteoblasts. The protein GoRab localises to the Golgi and appears to be an effector of the GTPase Rab6 since it binds the active GTP-bound form of Rab6 [202]. The Golgi apparatus consists of stacked cisternae, through which biosynthetic cargo proteins pass and are modified (Figure 1-13) [203]. It is also the site of synthesis of complex polysaccharides [204–206]. The function of

GoRab at the Golgi is unknown. However, a null mutant of GoRab has been identified in patients exhibiting gerodermia osteodysplastica [202]. A missense mutation resulting in similar phenotypes as the null mutant has also been described [207]. The phenotypes of this autosomal recessive disorder include osteoporosis, spontaneous bone fractures, above average joint dislocations, anomalies in the white matter of the brain but normal mental development. Patients have characteristic facial features with jaw hypoplasia, variable levels of growth retardation and wrinkly skin with severe elastin abnormalities [208–213]. GoRab was previously identified as an interactor with the pseudo protein kinase Scyl1, that is found in association with COPI vesicles and appears to be required for retrograde flow from the Golgi to the ER [214,215]. But the function of their interaction is unknown, particularly as Scyl1 localises to the *cis*-Golgi and GoRab polarises to the *trans*-Golgi-network (TGN) [202,216]. However, depletion of Scyl1 affects Golgi homeostasis which leads to an increased Golgi volume and surface area, decreased order in Golgi structure, and decrease in trafficking of the KDEL (Lysine/ Aspartic acid/ Glutamic acid/ Leucine) receptor by COPI [215]. But the Golgi polarity remains undisturbed. Similarly, the closely related Scyl3 associates with clathrin-coated vesicles [217], which are derivatives of Golgi transport vesicles. However, fibroblasts of patients carrying the GoRab null-mutant do not show any defects in Golgi or changes in the distribution of the Golgi proteins γadaption (a TGN marker), Rab6 (a *trans* Golgi marker) or GM130 (a *cis* Golgi marker) [202]. It is debatable whether GoRab should be classed as a Golgin since although it interacts with Rab6 and Golgi it has a single characteristic C-terminal coiled-coil domain, whereas Golgin proteins typically exhibit poorly structured coiled-coil domains throughout the whole protein. An understanding of the disease resulting from GoRab mutations is desirable, to understand how it leads to the typically ageing-related features on skin and bone, potentially by interfering with functional or secretory pathways [218]. A function of GoRab as a regulator of the MDM2-p53 feedback loop has also been suggested in which case it would function indirectly as a tumour suppressor [219]. GoRab triggers the self-ubiquitination and degradation of MDM2 (mouse double minute gene number 2) and thereby stabilising p53 levels [220–222]. This results in apoptosis, cell growth inhibition and tumour prevention [219].

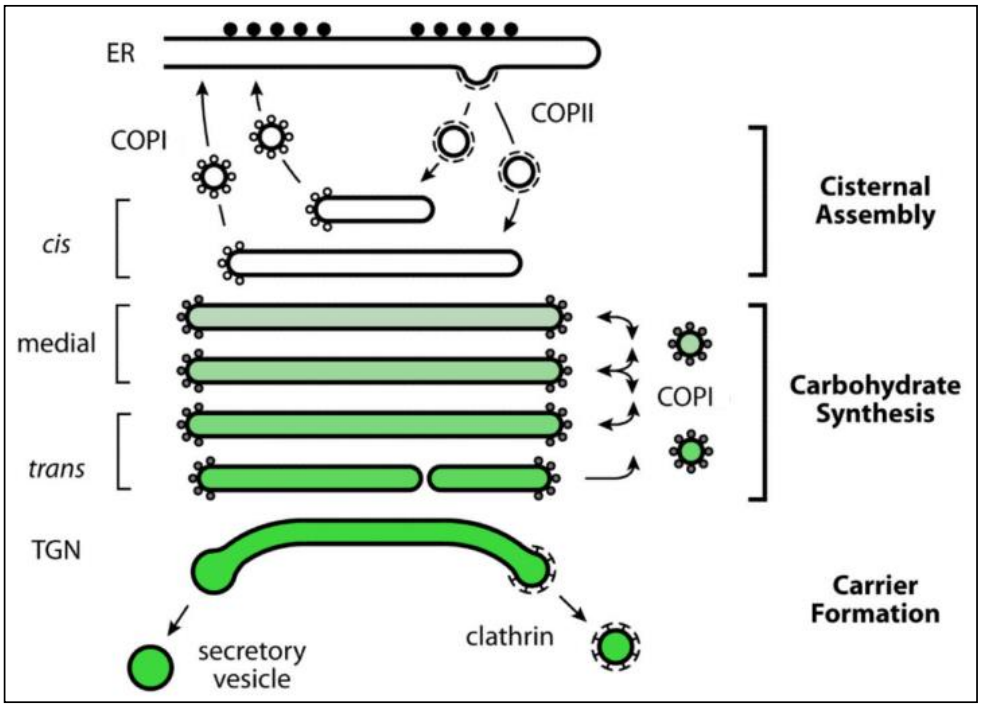

Figure 1-13 The currently proposed model of Golgi compartments and maturation. Structurally, COPI vesicles functions in the carbohydrate synthesis stage by transferring proteins between medial and *trans*-Golgi, as well as protein recycling from the *cis*-Golgi to the ER. COPII vesicles export proteins from the ER and bud into new *cis* Golgi cisterna, during the cisternal assembly stage. And carrier formation occurs at the TGN where cisterna disintegration leads to secretory and clathrin-coated vesicles. Figure reproduced with modifications and permission from [223].

Centrioles function not only at the core of centrosomal MTOCs but also as basal bodies to template cilia. There are two types of cilia, mobile and primary or non-mobile cilia. One obvious difference between the two forms is the composition of their axonemes. These originate from the basal body that is derived from the mother centriole of the cell's centrosome. Motile cilia have 9 peripherally arranged microtubule doublets plus one microtubule pair in their centre, which together with radial spokes and dynein arms enable its motility (9+2) [224]. Primary cilia assemble in G_0-phase and disassemble prior to mitotic entry. They consist only of 9 peripheral microtubule pairs and are missing the central microtubule pair (9+0) [224,225]. Primary cilia play an important part in cell signalling/signalling pathways [226,227] and regulate key processes during embryo development and tissue homeostasis, such

as differentiation, re-entry into the cell cycle, cell division and apoptosis. Therefore, defects in the cilia structure or function lead to developmental abnormalities and diseases affecting many organs, known as ciliopathies. These include skeletal defects, blindness, obesity, polycystic kidney disease, retinal degeneration, infertility, Bardet-Biedl syndrome and many more [228–234]. To assemble the primary cilium, the centriole pair migrates to the plasma membrane, allowing the mother centriole to function as the basal body by anchoring itself to the plasma membrane by its distal appendages (Figure 1-14A). This is followed by elongation of the axoneme from the mother centriole on the surface of the plasma membrane. It is also proposed that the mother centriole may also attach with its distal appendages to a nearby Golgi vesicle (Figure 1-14A). The axoneme of the primary cilium grows from the mother centriole then indents the vesicle, which in turn extends with the growing axoneme by budding and fusion with other secondary vesicles, while remaining connected to the appendages/transition fibres. The structure then migrates to the cell surface where the Golgi vesicle fuses to the plasma membrane; and the primary cilium emerges on the cell surface, where it matures to its full length [235,236]. In this second intracellular path of cilia assembly, the primary cilia is partially intracellular and protrudes from the ciliary pocket, that is a membrane invagination. This ciliary pocket is important in membrane trafficking and signalling pathways, and consists of the ciliary membrane, transition fibres (the transformed distal appendages of the mother centriole) and the ciliary necklace (proposed to be the original site of docking to the Golgi vesicle) [237]. Despite being continuous, the ciliary membrane has a denser and distinct composition compared to the plasma membrane [238–241]. It is a complex barrier that restricts the diffusion of proteins between the plasma and the ciliary membrane, and functions in the selection of proteins that can transit into the ciliary membrane and intra-ciliary space from vesicle trafficking [242–244]. The primary cilia does not synthesise proteins itself. Instead, proteins are supplied by vesicles that travel to, dock and fuse with the ciliary membrane [245]. These vesicles are derived from the Golgi [246,247] and carry ciliary specific cargo that is pre-sorted mainly in the *trans*-Golgi network [248]. Their delivery requires specific ciliary targeting signals needed for the sorting and fusion into the primary cilia. The movement of selected cargo in the mammalian primary cilia is organised by intraflagellar transport complexes (IFT) (Figure

1-14B), which are essential for the growth and maintenance of the primary cilia [242]. Proteins are transported by the anterograde path from the primary cilia base, along the microtubules of the axoneme and to the primary cilia tip, and by the retrograde path from the primary cilia tip to the base [249–254]. Transport is mediated by IFT-particles/IFT-trains together with ciliary building complexes, as well as kinesin 2 motor proteins for the anterograde path and cytoplasmic dynein 2 for the retrograde path [255–258]. The primary cilia has highly significant but highly diverse functions in signalling pathways, with one primary cilia being able to have different receptors and channels at the same or at different times. Signalling via primary cilia is used in sensory (Rhodopsin) and in a variety of developmental pathways in vertebrates (Hedgehog and Wingless) in response to, for example, mechanical force, hormones and growth factors [233,259–268]. The abnormal activation or lack of cilia and therefore disrupted cilia signalling is linked to abnormal cell division and cancer [269–281]. In summary, vesicle trafficking and protein sorting dictate the assembly of the primary cilia and participate in their function in development and cell-cycle regulation. This accounts for the pleiotropic phenotypes associated with ciliopathies.

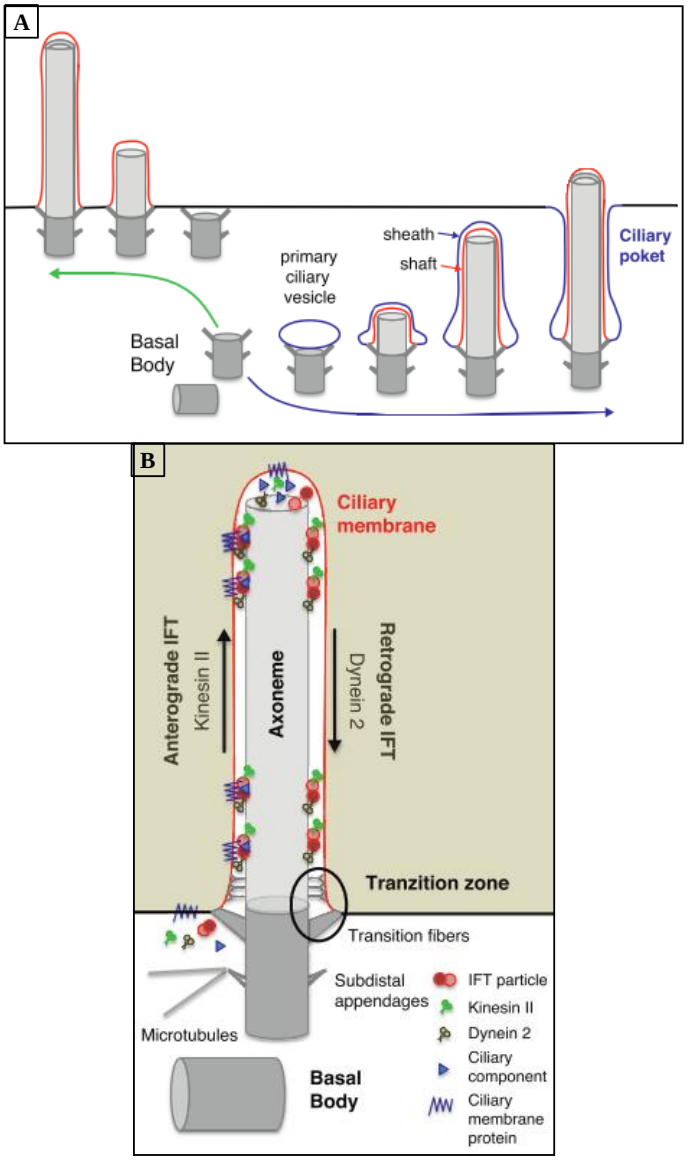

Figure 1-14 Cilia assembly and intraflagellar transport (IFT). (A) The mother centriole of a centriole pair functions as basal body in cilia assembly. Two different pathways are suggested. Firstly, the mother centriole anchors at the plasma membrane and the cilia is assembled from there on the cell surface. Alternatively, a Golgi vesicle is anchored by the distal appendages of the mother centriole in the cytoplasm, followed by the growth of the axoneme and the according growth of the vesicle by vesicle fusion. The growing cilia then migrates to the plasma membrane, where it is exposed to the cell surface by fusion of vesicle and plasma membrane. This creates the ciliary pocket at the cilia base. (B) Golgi vesicles are transported to the cilia, where they fuse with the ciliary membrane and release their cargo for anterograde and retrograde intraflagellar transport (IFT) by IFT particles and ciliary complexes, with the aid of Kinesin II and Dynein 2 respectively. The transition zone contains transition fibres and the ciliary necklace. It restricts protein diffusion from the cytoplasm, and functions as a protein selection barrier to the ciliary membrane and intraciliary space. Figure reproduced with modifications and permission from [245].

1.8 Aims of this thesis

The tight regulation of centriole duplication is important for the maintenance of genomic stability, but only little is known about the molecular regulation of centriole duplication. Therefore the overall goal of this thesis is to further elucidate the protein interactions at the centriole and the mechanisms that govern centriole duplication.

My aim was to identify the physical and functional interactions of the centriole duplication proteins. I approached this by re-analysing and performing *in vivo* protein purifications from cultured *Drosophila* cells and syncytial *Drosophila* embryos; performing a direct *in vitro* protein-protein interaction assay screen; and performing yeast-2-hybrid protein interaction assays to design a centriole protein network of protein-protein interactions in relation to their localisation at the centriole (Chapter 3).

I further aimed to specifically elucidate the interaction of Ana2 and Sas6, as it is known from *C. elegans* that their homologues Sas5 and Sas6 interact with each other and that a Sas5-Sas6-complex is recruited to the procentriole. My objective was to perform *in vitro* interaction studies of Ana2, Sas6 and Plk4, with the latter being the master kinase of centriole duplication. In collaboration with Dr. Dzhindzhev, I showed that Plk4 phosphorylates Ana2 at its STAN motif. Thus, I aimed to study non-phosphorylatable Ana2 versus phospho-mimicking Ana2 and to identify their effect on centriole duplication in *Drosophila* cell culture in collaboration with Dr. Dzhindzhev (Chapter 4). My next objective was to study the effect of Plk4-mediated Ana2-STAN phosphorylation on Ana2's ability to interact with other centriole duplication proteins and specifically Sas6 by combined phosphorylation and direct binding assays *in vitro* (Chapter 4). This identified an interaction between Ana2 and Sas6 that is dependent on Plk4-phosphorylation of the Ana2-STAN motif. This led me to determine the minimal structural domains within Ana2 and Sas6 that are necessary for protein-protein interaction. To this end, I generated truncated protein constructs of both proteins and tested their direct binding abilities *in vitro* (Chapter 4).

The studies of *in vivo* Sas6 purifications from *Drosophila* cell culture repeatedly identified the uncharacterised protein CG33052, which we named Dragon. Its human homologue GoRab localises to the Golgi. My aim was to confirm or deny Dragon localisation at the Golgi and the centrosome. Additionally, I aimed to identify if Dragon is essential for centriole duplication by studying its effect on centrosome numbers after Dragon depletion; and to determine if Dragon interacts directly with the centriolar cartwheel protein Sas6 (Chapter 5). Centriolar localisation of Dragon by structured illumination microscopy was shown in collaboration with Dr. Tzolovsky. After showing that Dragon localises to the centriole and directly interacts with the centriolar cartwheel protein Sas6, I aimed to identify the smallest protein domains of Sas6 and Dragon necessary for their interaction (Chapter 5). My next objective was to generate a Dragon mutant that abolishes interaction with Sas6 and study its effect on centriole duplication by performing rescue experiments in *Drosophila* cell culture (Chapter 5). For my final objective I asked whether there is a similar requirement for the human homologue GoRab for centriole duplication (Chapter 5).

Chapter 2

Materials and Methods

2 Materials and Methods

2.1 Cloning

2.1.1 Gateway cloning to generate tagged protein constructs

Gateway® cloning is an Invitrogen™ cloning system, applying recombination att sequence sites and BP and LR Clonase® enzyme mixes to transfer DNA fragments between plasmids and generate tagged proteins.

Full-length cDNAs (BDGP Gold Collection, *Drosophila* Genomics Resource Center) were amplified by PCR, using Pfu Ultra™ DNA Polymerase AD (Agilent, 600389-51), followed by agarose gel electrophoresis analysis and gel extraction (QIAquick® Gel Extraction Kit, QIAGEN, 28706). Utilised were the following cDNAs from the *Drosophila* Genomics Resource Centre (DGRC): Ana1 (LD07765 and IP16240 to generate a full-length Ana1 cDNA), Ana2 (LD22033), Asterless (GH02902), Bld10 (LD35990), Cep97 (RE26466), Rcd4 (SD16838), Sas6 (AT29216), Plk4 (RE70136), Dragon (RE68977). To generate the pENTR clones, the cDNA products were recombined with pDONR221 (Invitrogen™, Thermo Fisher Scientific, 12536-017) using BP Clonase® II Enzyme Mix (InvitrogenTM, Thermo Fisher Scientific, 11789-020). The fusion vectors were transformed into Library Efficiency® DH5α™ Competent Cells (InvitrogenTM, Thermo Fisher Scientific, 18263-012), amplified, purified (QIAprep® Spin Miniprep Kit, QIAGEN, 27106) and sequenced (Source BioScience LifeScience or GATC Biotech). To generate the pDEST clones, the pENTR clones were recombined with the Gateway® destination vectors, using LR Clonase® II Enzyme Mix (InvitrogenTM, Thermo Fisher Scientific, 11791-100). The *Drosophila* Gateway Vectors were used to generate expression vectors that drive expression of proteins with the N- or C-terminal tag eGFP (pAGW, pAWG, Thermo Fisher Scientific), 3xFLAG (pAFW, pAWF, Thermo Fisher Scientific), 6xmyc (pAWM, Thermo Fisher Scientific), 6xHis (pDEST42, Thermo Fisher Scientific), GST (pDEST24, Thermo Fisher Scientific) or MBP (pKM596,

Addgene plasmid 8837). Additionally, pAct5c-PrA and pMT-cPrA (with the copper-inducible *Metallothionein* A (CG9470) promotor) were used, that were originally generated in the lab [282]. To generate plasmids that express untagged proteins, the pENTRs with the protein sequence and a C-terminal STOP codon were recombined into destination vectors for C-terminal tagging. The STOP-codon between the coding sequence and the tag leads to protein translation without the tag.

2.1.2 Regular cloning to generate constructs for Yeast-2-Hybrid method

PCR products that carry specific restriction enzyme sequences upstream and downstream of the protein sequences were amplified and cloned into the yeast-2-hybrid vectors pGBT9 and pGAD424. Pfu Ultra™ DNA Polymerase AD (Agilent, 600389-51) was utilised for the PCRs. Digests were performed consecutively or simultaneously, depending on the buffer conditions of the restriction enzymes used. The digested vectors were additionally treated with CIP (Alkaline Phosphatase, Calf Intestinal; New England BioLabs, M0290S) for 1 hour at 37°C, which catalyses the dephosphorylation of the 5' and 3' endings of the linearised vectors to prevent religation, followed by 15 minutes at 75°C to inactivate the CIP enzyme. The linearised vectors and digested PCR products were subjected to ligation at 16°C over night, using T4 ligase and reaction buffer (10x reaction buffer is 300mM Tris-HCl (pH 7.8 at 25°C), 100mM $MgCl_2$, 100mM DTT and 10mM ATP) (Promega, M1801). The ligation reaction was transformed into XL10-Gold ultracompetent cells (Stratagene, Agilent Technologies, 200314) according to the manufacturer protocol.

2.2 Site-directed mutagenesis

Table 2-1 Primers used for site-directed mutagenesis reactions. Listed are the forward (FW) and reverse (RV) primers applied in site-directed mutagenesis reactions of protein vectors to create the listed mutated protein (name). Blue represents final mutated sequence; red represents deletion between the two highlighted nucleotides.

To introduce point mutations or deletions within Dragon, the QuikChange II XL Site-Directed Mutagenesis Kit (Agilent Technologies, 200521) was used with Dragon cDNA or Dragon+STOP in pDEST42 (invitrogen™, Thermo Fisher Scientific, 12276010). The mutagenesis reaction mixes of 25µl final volume contained: 50ng DNA, 1x buffer, 600µM NTPs, 240nM forward primer, 240nM reverse primer, 1.5µl Quik Solution, 0.5µl *Pfu* Ultra high-fidelity DNA Polymerase; and the following temperature cycling program was used: 1. 95°C for 1 minute, 2. 18x cycles of 95°C for 50 seconds, 60°C for 50 seconds and 68°C for 3 minutes, 3. 68°C for 10 minutes, 4. Final storage at 4°C. The method uses the supercoiled

double-stranded DNA vector and two primers that are complementary to opposite strands of the vector and contain the desired mutation. The primers are extended during the temperature cycles and contain staggered nicks. After the cycling program, the template DNA was digested by DpnI enzyme for 1 hour at 37°C, which targets for methylated and hemimethylated DNA (target sequence: 5´-Gm6ATC-3´). The remaining generated nicked vector products were transformed into DH5α cells.

2.3 Immuno-Histo-Staining and Microscopy

2.3.1 Immuno-Histo Stainings

For immune-staining of *Drosophila* cell culture 22 x 22 mm cover slides (VWR, 48376-049) were used. Therefore, the cell culture concentration was counted with a Hemocytometer and diluted to 500,000 to 800,000 cells per ml culture. Cover slides were pre-treated with concanavalinA (ConA, Sigma), which stretches the cells horizontally and allows an easier observation of the centrioles. The cells were incubated on the cover slide for 3 hours at 25°C before fixation with ice cold methanol. To fix the cells, the medium was taken off, 3ml ice cold methanol (left on dry-ice for 30 minutes beforehand) was flushed quickly onto the cover slides and remained on dry ice for 5 minutes. The methanol was taken off quickly and the cover slides were washed twice with 1x PBS. For long term storage, PBS-0.1%NaN_3 was added to prevent bacteria growth. To prepare the cells for staining, the cover slides were washed with PBS-0.1%TritonX-100 and transferred onto parafilm. The cells were blocked with PBS-10%FBS-0.1%TritonX-100 for 1 hour at room temperature, followed by incubation with primary antibodies (in PBS-10%FBS-0.1%TritonX-100) over night at 4°C, 3 washes with PBS-0.1%TritonX-100, and incubation with secondary antibodies (in PBS-10%FBS-0.1%TritonX-100) for 1 to 3 hours at room temperature (commonly Alexa Fluor® antibodies from Novex™ (Thermo Fisher Scientific) were used). After incubation, the cover slides were washed 3 times with PBS-0.1%TritonX-100 and stored in 1x PBS until mounting the same

day. The cover slides were briefly rinsed in ddH_2O before mounting to microscope slides with VECTORSHIELD mounting medium for fluorescence with DAPI (for DNA staining) (Vector Laboratories, H-1200) and nail varnish was used to seal off the edges.

2.3.2 Microscopy

2.3.2.1 Structured illumination microscopy

The method was applied in collaboration with Dr. Tzolovsky and as describes in [24]. In short, the OMX-V3 system was used with a 63x/1.4NA oil Olympus lens to acquire super-resolution images (512x512ppi), followed by images being reconstructed and registered using the package SoftWorx Linux and processing of the images to obtain the maximum intensity projections. Final figures were cropped and assembled in Photoshop v6.

2.3.2.2 Fluorescent microscopy

Microscopic analyses of *Drosophila* cells and U2OS cells after histo-immuno-staining were performed on a Carl Zeiss Axiovert 200M microscope with 40x/1; 63x/1.25 and 100x/1.4 Plan Apochromat objectives. Acquiring of images was performed with a Photometrics Cool SNAP HQ2 camera, analyses of images were performed with the Metamorph software (v7.7).

2.4 Western Blot

For Western Blotting, proteins were run on a SDS-PAGE gel and transferred onto Hybond-ECL membran (GE Healthcare, RPN3032). Membranes were stained with Amido Black to visualise total protein. The membranes were then blocked for 1 hour in PBS-0.1%Tween-4% milk solution, followed by incubation over night with the primary antibody in PBS-0.1%Tween-4% milk solution at 4°C. The membranes were washed 3 times for 5 minutes in PBS-0.1%Tween and incubated for one hour with the secondary peroxidase conjugated

antibody in PBS-0.1%Tween-4% milk solution at 4°C. After 3 washes in PBS-0.1%Tween for 5 minutes at room temperature the proteins were detected using Immobilon Western Chemiluminescent HRP Substrate reagent (WBKLS0500, Millipore). For this membrane was incubated with the mixed solutions (5ml ddH_2O, 2.5ml substrate solution, 2.5ml luminol solution) for 5 minutes, the majority of the solution was aspirated off and the membrane developed in the dark room.

Table 2-4 Summary of primary antibodies that were used in Western Blot analyses.

2.5 Expression and purification of tagged proteins from *E. coli* for *in vitro* assays and antibody generation

2.5.1 Expression and purification of tagged proteins from *E. coli*

Proteins were tagged with GST (Glutatione S-Transferase) or MBP (Maltose Binding Protein) using gateway cloning technology and transformed into Chemically Competent *E. coli* cells One Shot® BL21 Star™ (DE3) or BL21 Star (DE3) pLysS (Thermo Fisher Scientific). Colonies were tested for protein expression by inoculation of an overnight culture at 37°C,

220 rpm, followed by dilution to 1:50 and growth of the culture until it reached an OD of 0.4 to 0.6. At this time point a 1 ml sample of bacteria culture was taken for further analysis on SDS-PAGE and 1mM IPTG was added to the main culture to induce protein expression. The culture was left at 37°C and 1 ml culture samples were taken at different time points, up to 6 hours after induction, to analyse the level of protein expression on SDS-PAGE. After the timed protein expression, the cell cultures were centrifuged at 8600 rpm for 12 minutes, resuspended in 1x PBS and instantly stored at -20°C or -80°C. The samples for SDS-PAGE analysis were centrifuged at 13.000 rpm for 1 minute, the pellets were resuspended in PBS/1%Benzonase, left for 1 minute at RT, followed by adding 3x sample buffer containing 15%β-Mercaptoethanol to the sample and boiled at 96°C for 5 minutes.

Alterations of the expression conditions were undertaken where the above described protocol did not result in efficient protein expression. Expression levels were tested at 25°C or 16°C with increased expression times of up to 20 hours. The construct containing the HsSas6 protein sequence was kindly provided by Dr. Tzolovsky, followed by PCR to attach att overhangs for Gateway® cloning into pDONR221 and the expression construct pDEST15 (N-terminal GST tag).

For the protein purification, the bacteria suspension was defrosted and 1x Protease Inhibitor mix (cocktail tablets, complete EDTA-free, Roche, 11873580001), 10% PMSF (Sigma, 93482), 4% TritonX-100 (Sigma, T8787) and 10% Glycerol (Sigma, G5516) were added. In the case of Sas6 purification, PMSF was not added. Additionally, for the proteins stored on resin described in chapter 3, Sodium lauroyl sarcosinate (Sarkosyl, Sigma, 61747) was used instead of Glycerol, to increase solubility of GST fusion proteins [283]. The bacteria mix was then sonicated at 4°C until it was not viscous but of a fluid character, followed by a centrifugation step at 18,000 rpm for 30 minutes, 4°C. To purify the fusion protein, the according resin was added to the supernatant, which contains the soluble fusion protein, and rotated at 4°C for 2 to 3 hours. For GST fusions, Glutathione Sepharose 4B (GE Healthcare, 17-075601) and for MBP fusions, Amylose resin (BioLabs E8021L) were used. Each of the resin solutions were washed in PBS-2%TritonX-100 (T-PBS). For storage of the proteins on

beads, 250µl beads baid volume were used (proteins bound to resin was stored at -20°C in 1x PBS with 50% glycerol); and for final protein elutions, 500µl beads baid volume were used for binding. After the binding, the beads were washed once with 0.5% T-PBS, once with 0.1% T-PBS and twice with Wash Buffer (50mM TrisHCl, 150mM NaCl, 0.1% TritonX-100). For further experiments with tagged protein bound to beads, they were stored at -20°C in 1x PBS with 50% glycerol. For elution of the proteins off the beads, Elution Buffer (10mM TrisHCl, 30mM NaCl, 0.02% TritonX-100, plus 15mM L-Glutathione for GST tagged proteins or 15mM Maltose for MBP tagged proteins) was added as twice the volume of the resin bait volume. Each protein was eluted 3 times at 4°C on a rotating wheel, for 2 hours or overnight for the first and second elution and for 2 hours for the third elution, and stored at -20°C. For use of the protein as an antigen in the generation of antibody, the protein was dialysed against 1x PBS overnight and again for 10 hours in fresh 1x PBS. In the case of MBP-Plk4-T172E and MBP-Plk4-T172E-K43M; the proteins were eluted in kinase buffer (20mM Na-HEPES pH7.5, 100mM NaCl, 10mM $MgCl_2$, 10mM $MnCl_2$, 1mM DTT), supplemented with 15mM D-Maltose, and stored at -80°C in Plk4-Kinase Buffer supplemented with 50% glycerol. Concentrations were measured by spectrophotometry and quality was analysed by SDS-PAGE.

Table 2-6 Summary of expressed and purified proteins as of their first appearance in the chapters of this thesis.

Chapter 3	Chapter 4	Chapter 5
GST	MBP-Plk4-T172E	GST-Sas6

2.5.2 Lambda-phosphatase bandshift assay

The λ-phosphatase bandshift assay was used to analyse the kinase activity of purified MBP-Plk4-T172E by its migration on SDS-PAGE. MBP-Plk4-T173E was resuspended in λ-phosphatase buffer (1x NEBuffer, 1x $MnCl_2$ Buffer, up to with ddH_2O, all NEB, P0753) and half the sample was treated with exogenous λ-phosphatase (NEB, P0753) for 1 hour at 30°C, followed by adding 3x sample buffer containing 15%β-Mercaptoethanol and boiling of the sample at 96°C for 5 minutes. Samples were subjected to SDS-PAGE and compared to the migration of kinase dead MBP-Plk4-T172E-K43M.

2.5.3 Antibodies generation and purification

Protein expression, purification and elution for the production of antibodies was performed as previously described (section 2.5.1). Antibodies applied in this study: MBP-Ana2 (full length) and GST-Sas6-C (aa236-472). The concentrated protein (150µg for 4 to 6 injections) was send to IMBC - instituto de biologia molecular e cellular, Porto, Portugal; to be used as antigen to generate IgG immunoglobulins specific for the antigen in rat. The received rat serum was stored in 50% glycerol at -80°C and used for antibody purification. The purification of the antibodies was performed as an IgG purification on rProteinA : ProteinG Sepharose (GE Healthcare, 17-1279-01, 17-0618-01 respectively) and were done small scale with 200µl resin suspension and 1000µl serum. This method allowed purification of all the IgGs present in the serum. The principle for the purification of IgG, IgG fragments and subclasses, is the high affinity of proteinA and proteinG for the Fc region of polyclonal IgG-type antibodies. ProteinA and ProteinG are bacterial proteins from *Staphylococcus aureus* and *Streptococcus* respectively, which were coupled to sepharose and can be used to isolate IgGs from serum. ProteinA has five regions for the Fc region of IgG to bind. Additionally, the used rProteinA (recombinant protein A) has been engineered to include a C-terminal cysteine which enables a single-point coupling to sepharose, allowing an increased binding capacity. ProteinG is a cell surface protein from Group G streptococci and a type III Fc-receptor, which binds through a non-immune mechanism. Compared to ProteinA, it binds more strongly to several polyclonal IgGs. Therefore a mixture of 50% rProteinA : ProteinG was used for serum from rat (anti-Ana2 and anti-Sas6). For the purification of sheep serum (anti-Plk4) only ProteinG and for the purification of rabbit serum (anti-Asterless and anti-Ana2-N) only rProteinA was used.

For the purification, the serum was diluted 10 times with PBS and centrifuges for 10 minutes at 14.000 rpm, 4°C to remove aggregates. Then it was mixed with the resin for binding on a rotating wheel for 60 minutes at 4°C, followed by two wash steps with PBS-0.1%TritonX-100 and two rinses with 1x PBS. The elutant was 0.1M Glycine-HCL pH3, which was added to the resin, mixed for 10 to 20 seconds and then removed and neutralised with 1M Tris-HCl

pH8. Each antibody was eluted up to 4 times to win the highest protein concentration. For long term storage, the antibodies were concentrated by dialysing against a 50% Glycerol-PBS solution at 4°C overnight.

2.6 *In vivo* assays and Mass spectrometry

2.6.1 *In vivo* ProteinA and GFP-trap purification from *Drosophila* cell culture

For the identification of protein complexes *in vivo*, a combination of the methods of cell culture, single step ProteinA affinity or GFP trap purification and Mass Spectrometry has proven to be successful in mitotic and cytokinetic complexes. The method is based on the tagging of a bait protein with two IgG binding domains of Protein A or GFP, followed by stable expression in *Drosophila* cell culture, and isolation of the tagged bait protein together with its interacting partners by a single affinity purification step. The isolated protein complexes were then analysed Mass Spectrometry.

The cells for Mass Spectrometry analysis were expanded to 6 or 8 cell culture flasks of 175cm^2, using Express Five® SFM (1x) cell culture medium (Gibco^{TM}, Thermo Fisher Scientific, 10486-025) supplemented with 2mM L-glutamine (Gibco^{TM}, Thermo Fisher Scientific, 25030), and 100 U/ml penicillin and 100µg/ml streptomycin (Gibco^{TM}, Thermo Fisher Scientific, 15140). The cells were grown at 25°C until confluent, followed by passage. Cells were treated with 25µM MG132 for up to 5 hours to inhibit proteasomal degradation. For proteins which express from a pMT promoter, 1mM $CuSO_4$ was added to the medium for 22 hours to induce expression of the protein. 50% of each cell line was additionally treated with 50nM okadaic acid for 9 to 16 hours to inhibit the protein phosphatase PP2A and keep proteins in their phosphorylated state.

2.6.1.1 ProteinA purifications

For ProteinA purifications, the cells were harvested in PBS, resuspended in cold extraction buffer (75mM Na-HEPES pH7.5, 150mM NaCl, 2mM $MgCl_2$, 0.1%NP-40, 5mM DTT, 2mM EGTA, 5% glycerol, 1 tablet complete protease inhibitor per 50 ml), homogenised on ice and centrifuged at 4°C to pre-clear the soluble material. The supernatant was transferred to new tubes and magnetic rIgG-Dynabeads M-270 Epoxy (Invitrogen™, Thermo Fisher Scientific, 143.02D) were added. The mixture was incubated on a slowly spinning wheel at 4°C for 2 hours, to allow the rabbit IgG to bind to the complexes associated with the ProteinA tagged bait. After incubation, the beads were washed 5 times with extraction buffer, followed by elution using an elutant (0.5M NH_4OH, 0.5mM EDTA). For the analysis of the proteins, the eluted protein samples were desiccated to a volume of 100µl and an aliquot was taken for analysis using the SilverQuest™ Silver Staining Kit (Novex™, Thermo Fisher Scientific, LC6070). The proteins were then precipitated in small volumes with Acetone, dried in a speedvac centrifuge (Eppendorf, Concentrator 5301) and send for gel-free mass spectrometry analysis (Mass Spectrometry Laboratory, Institute of Biochemistry and Biophysisc, Warsaw, Poland).

The following purifications by Cunha-Ferreira, Dzhindzhev, Psternak, Schneider* and Weiskopf were reanalysed in chapter 3 and 5: pMT-Ana2-PrA*, pAct5-PrA-Ana2+pMT-Plk4*, Act5-PrA-Asl, Act5-Asl-PrA, Act5-Asl(aa531-994)-PrA, pMT-PrA-Cep97, pMT-Cep97-PrA, pMT-PrA-CP110, pMT-CP110-PrA, Act5-PrA-Plk4, pMT-PrA-Plk4, pMT-Rcd4-PrA, pMT-Sas4-PrA, pMT-PrA-Sas6. Additional purifications were performed but did not yield centrosomal duplication proteins in complex with the bait*: pAct5-PrA-Ana1, pAct5-Ana1-PrA, pAct5-PrA-Ana2, Act5-Ana2-PrA+pMT-Plk4, pAct5-PrA-Bld10, pAct5-PrA-Sas6. The constructs and cell lines were kindly provided by Dr. Dzhindzhev.

2.6.1.2 GFP-trap purifications

The GFP-trap purifications were performed in the cold room at 4°C and all reagents were kept at 4°C if not otherwise stated. The confluently grown *Drosophila* cells in 6x175cm^2 flasks (Corning®, 431079) were harvested with a cell scraper and centrifuged at room temperature and 900g for 5 minutes, followed by a 1x PBS wash and combining of all the cells into one 50ml falkon tube (Greiner Bio-One, 227261). The cells were then resuspended in 8ml Lysis Buffer 1 (20mM Tris pH7.5, 150mM NaCl, 2mM $MgCl_2$, 1mM DTT, 0.1% NP-40, 5% glycerol, 1x EDTA-free complete protease inhibitor cocktail (PIC, Roche) and 1mM PMSF (for samples other than tagged Sas6 purifications)) and homogenized at power 6 for 5-6 times for 30 seconds with breaks of 15 seconds (Fisherbrand PowerGen 125, FB70300). The lysate was clarified at 10,000 rpm for 15 minutes at 4°C. In the meantime the GFP-trap agarose bead suspension (ChromoTek, gta) was pre-equilibrated: 120µl of beads were added to 10ml LB1 and gently mixed 4-6 times, followed by centrifugation at a maximum of 2400g for 3 minutes at 4°C with a low deceleration speed and removal of the final supernatant. The supernatant of the cell lysate was then mixed with the GFP-trap beads and incubated on a rotating wheel (15-20 rpm) for 2-3 hours at 4°C. Thereafter, the beads were centrifuged at a maximum of 2400g for 3 minutes at 4°C with a low deceleration speed and the supernatant was removed. The beads were then washed twice in 10ml cold LB1 at 20rpm for 10 minutes, at 4°C; followed by transfer of the beads to a new pre-chilled Falcon tube and two wash steps in 10ml LB2 (same as LB1 but without PMSF and PIC). Beads were then transferred to a 1.5ml Eppendorf tube, adjusted to 1ml with LB2 and send for mass spectrometry. The protein complexes were mixed with 1x Laemmli sample buffer and analysed by Western Blotting.

The GFP-trap purifications from *Drosophila* cell culture stably expressing pMT-Dragon-GFP or pUb-GFP-Dragon (kindly provided by Miss Chu) were performed and analysed. Additionally, the purifications of pMT-PrA-Sas6 by Dr. Dzhindzhev was reanalysed.

2.6.2 Large scale collection and *in vivo* GFP-trap purification from *Drosophila* syncytial embryos

2.6.2.1 Large scale *Drosophila* embryo collection

For the large scale collection of 0-4 hours old syncytial *Drosophila* embryos that express poly-Ubiquitin-GFP-Dragon (flies kindly provided by Miss Chu), the flies were expanded to 9 large maintenance bottles and transferred into 2 large population cages (Genesee Scientific, FS59-104) for the collection of 1g of fresh embryos for GFP-trap purification. The population cages were kept at a 12/12 hours reversed light/dark cycles, with a room temperature of 25°C and a room humidity of 70%. On day 1 (morning), 2 chippy trays with grape juice agar and yeast paste were added to each cage, and replaced every 12 hours for a period of 48 hours. This stimulates the flies to the food-rich environment, which avoids eggs retainment and hence, synchronised egg laying. On day 3 (morning), a final change of chippy trays with yeast paste was added to the population cages for one hour to finalise full synchronisation. Thereafter new chippy trays with small amounts of yeast paste were added and replaced every 4 hours. The embryos were collected from the chippy trays with fine brushes and washed in mesh sieves with dH_2O, followed by a quick drying step with a paper towel pressed against the underneath of the sieve. For dechorionation, the embryos were transferred into a small beaker with 60ml 50% bleach (Kemtec) for 3-5 minutes, which was gently swirled manually. The dechorionated embryos were transferred into a small mesh sieve, washed with water, then wash buffer (0.7%NaCl+0.01% TritonX-100), to remove the vitelline membrane, and transferred into 2ml tubes and briefly centrifuged for collection. For long term storage, the decorionated embryos were frozen in liquid nitrogen.

2.6.2.2 *In vivo* GFP-trap purification from *Drosophila* syncytial embryos

1g of fresh *Drosophila* syncytial embryos (0-4 hours) expressing poly-Ubq-GFP-CG33052 were homogenised with a Dounce tissue grinder (Wheaton) in 10ml Extraction Buffer (EB: 20mM Tris-HCl pH7.5, 150mM NaCl, 2mM $MgCl_2$, 0.5mM Na-EGTA pH8, 1mM DTT (dithiothreitol), 0.1%NP-40, 5% glycerol, 1mM PMSF (phenylmethanesulfonyl fluoride), EDTA-free complete protease inhibitor cocktail (Roche)) at 4°C. 10ml of EB were then added to the sample, which was then vortexed for 10 seconds and passed through a needle and pre-chilled syringe three times, followed by a centrifugation step at 5000g for 20 minutes at 4°C. The supernatant was carefully transferred to a new tube, avoiding to remove any white fatty matter with it, and mixed with pre-equilibrated GFP-trap agarose beads (50-100µl per sample, gently mix in 5ml EB in 15ml conical tubes, sediment beads at 500g for 3 minutes at 4°C) for 30-150 minutes, at 18 rpm on a spinning wheel at 4°C. Thereafter, the beads were washed four times in 10ml Wash Buffer (same as EB) for 5 minutes each, at 4°C; sedimented and transferred to a new 15ml conical tube, washed two times in 10ml Final Wash Buffer (FWB: 20mM Tris-HCl pH7.5, 150mM NaCl, 2mM $MgCl_2$, 0.5mM Na-EGTA pH8, 1mM DTT) by gently rotating for 10 minutes at 4°C; again sedimented, transferred and twice washed with FWB; and finally all buffer was removed, and beads were stored at 4°C until on-beads tryptic digestion and mass spectrometry analysis.

The purifications of pUb-Sas6-GFP from *Drosophila* syncytial embryos by Dr. Dzhindzhev were reanalysed; these purifications were performed with normal NaCl concentration or with a high 440mM NaCl concentration and plus/minus okadaic acid.

2.6.3 Mass spectrometry and Phospho-peptide/residue mapping

The Mass Spectrometry data was generated by Dr. Dubski at the Mass Spectrometry Laboratory, Institute of Biochemistry and Biophysics, Pawinskiego 5a, 02-106, Warszawa, Poland. GST-Ana2 protein was phosphorylated by active Plk4 *in vitro* and ProteinA-Ana2

was phosphorylated by co-expressed non-degradable $Plk4^{ND}$ in *Drosophila* cell culture (*in vivo*). The protein samples were digested with trypsin (Promega V5111) and the peptide mixtures were analysed by LC–MS/MS (high-performance liquid chromatography tandem mass spectrometry) using Nano-Acquity (Waters) LC system and Orbitrap Velos mass spectrometer (Thermo Electron Corp.). The raw data was then analysed by Mascot Distiller followed by Mascot Search (Matrix Science) against the FlyBase database. The values of Mascot scores for individual proteins ('Protein score') and 'number of identified peptides' were analysed as a measure of ability for certain baits to co-purify with the prey protein. The Mascot score is a statistical score that represents how well the experimental data matches the database sequence (FlyBase). A 95% confidence level is required to identify a positive protein. The final Mascot score is generated from the summed scores of peptide masses and peptide fragment ion masses for the individual peptides that match a given protein.

2.7 Yeast-2-Hybrid – testing for direct interactions in an *in vivo* system

For the Yeast-2-Hybrid assay, each protein sequence was cloned into the vector pGBT9 and pGAD424 and then co-transfected into the yeast strain AH109. The method is based on the activation of the GAL promotor by its transcription factor, which is split into Binding Domain (BD) and Activation Domain (AD). The bait plasmid (pGBT9) contains the GAL4 DNA-Binding Domain (BD) and the prey plasmid (pGAD424) contains the GAL4-Activation Domain (AD). When proteins cloned into these plasmids interact directly with each other, they bring the BD and AD together, allowing for GAL promotor transcription and translation, which leads to colonies that grow on X-α-GAL to turn blue (colonies turn blue after up to 6 days at 30°C when a protein interaction occurs). If the co-transformation has been successful but the proteins do not interact with each other, the yeast can grow on the selection plates, which select for -Leu (pGD424) and –Trp (pGBT9), but they stay white and do not turn blue. If a transformation has not been successful with neither or only one of the plasmids, then the yeast strain cannot grow on the selection media.

For the co-transformation, the overnight culture of AH109 is diluted in 330ml YPD medium with OD600 = 0.3, then grown until OD600 = 0.6. The cells are centrifuged at RT, 1000g, 5 minutes, resuspended in 1x TE, centrifuged and resuspended in 1.5ml 1x TE/ 1x LiAc. 100µl of competent cells are added to 0.1µg plasmid DNA 1 + 0.1µg plasmid DNA 2 + 0.1mg carrier DNA and mixed by vortexing. 600µl of PEG/LiAc solution are added and the tube is vortexed for 10 seconds. The cells then incubate at 30°C, 220 rpm for 30 minutes. 70µl of DMSO is added to the cells and gently inverted, followed by a heat shock for 15 minutes at 42°C and 2 minutes on ice. Then the cells are resuspended in 1x TE, 100µl are plated on dropout media containing X-α-GAL and the plates are incubated at 30°C for up to 6 days.

Table 2-7 List of proteins that were cloned into pGAD424 or pBGT9 vectors. The vectors carry a GAL4-AD (activation domain) or GAL4-BD (binding domain) respectively; including plasmids used as positive and negative controls. The plasmids were used in yeast-2-hybrid interaction studies.

Vector	Domain	Proteins	Control
pGAD424	GAL4-AD	Asl, Ana2, Bld10, Cep97, CP110, Plk4, Rcd4, Sas4, Sas6, Polo and Spd2	-
pBGT9	GAL4-BD	Ana2, Bld10, CP110, Sas4 and Sas6	-
pGAD424	GAL4-AD		negative
pBGT9	GAL4-BD		negative
pGAD424	GAL4-AD	Mis12	positive
pBGT9	GAL4-BD	Nnf1a	positive
pGAD424	GAL4-AD	Nnf1a	positive
pBGT9	GAL4-BD	Mis12	positive

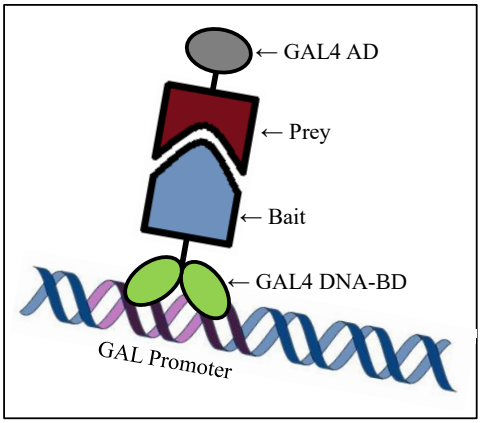

Figure 2-1 Schematic diagram of the GAL promotor activation in the yeast-2-hybrid system. Binding of bait and prey protein bring together the GAL4-AD and GAL4-BD which forms the transcription factor for the GAL promotor.

2.8 *In vitro* binding assays

2.8.1 *In vitro* binding assay

For the analysis of *in vitro* protein-protein-interactions, the methods of *in vitro* transcription – translation (IVTT), followed by binding assays and pull-downs were performed.

The method is divided into the production of two different sets of reagents, ^{35}S-Methionine-labelled proteins and tagged protein immobilised on resin (section 2.5.1). Every protein to analyse was amplified from cDNA in T7 containing promotors or from PCR products that carry the T7 promoter sequence 5'-GAATTAATACGACTCACTATAGGG-3', the Kozak sequence 5'- AGAGCCGCCACC-3', the start codon for protein transcription and the protein coding sequence. Alternatively, proteins were amplified from the pHY22 vector which contains a T7 promotor followed by the start codon and protein sequence. For the transcription-translation reaction, the TnT® T7 Quick Coupled Transcription/Translation System kit (Promega, L1170) was used. It contains a TnT® T7 Quick Master Mix, to which radioactively labelled ^{35}S-Methionine (Perkin Elmer, NEG709A001MC), RNasin Plus RNase Inhibitor (Promega, N2611), T7 TNT PCR Enhancer, protease inhibitor cocktail and the cDNA, PCR product or pHY22 vector with the protein sequence were added. The reaction of *in vitro* transcription/translation reaction was performed in a volume of 50µl, at 30°C for 30 to 120 minutes. The synthesised and radioactively labelled proteins were then used for binding assays. The cDNAs of *Drosophila* centriole duplication proteins were sourced from the BDGP Gold Collection, *Drosophila* Genomics Resource Center. The human GoRab variant 3 was sourced from Source Bioscience, followed by PCR to amplify att sequence overhangs and include a STOP codon after the protein sequence for Gateway® cloning into pDEST42 (C-terminal His tag). The human GoRab variant 1 was generated by PCR from a U2OS cDNA cell library, which was kindly provided by Dr. Lipinszki.

For the binding assay, each tagged protein on beads (bait) was mixed with each radioactively labelled protein (prey) in individual reactions in 800µl Binding Buffer (50mM

Hepes pH7.5, 1mM EGTA, 1mM $MgCl_2$, 1mM DTT, 100mM NaCl, 0.1%Triton X-100, 1x Protease Inhibitor, 0.5mg/ml BSA). The mixture rotated on a spinning wheel for 30-60 minutes at RT, followed by 3x5 minutes washes in Wash Buffer (50mM Hepes pH7.5, 1mM EGTA, 1mM $MgCl_2$, 1mM DTT, 100mM NaCl, 0.1%Triton X-100), to remove the radioactively labelled proteins that were not directly bound to the protein on beads. The resins were transferred into new tubes and 3xsample buffer containing 15%β-Mercaptoethanol was added. To analyse if interaction occurred between 2 proteins, the resin samples were subjected to SDS-PAGE followed by Western Blot or the drying of the SDS-PAGE, exposure to hypersensitive film (Kodak BioMax MS film, 8222648) at -80°C and autoradiography. The resulting exposure signals were categorised into: no interaction (-), weak interaction (+), interaction (++) and strong interaction (+++). Visually compared were the 'input versus negative control' signal, which in turn support the comparison of the 'interaction versus input' and 'interaction versus negative control' signal, to categorise the analysed interaction.

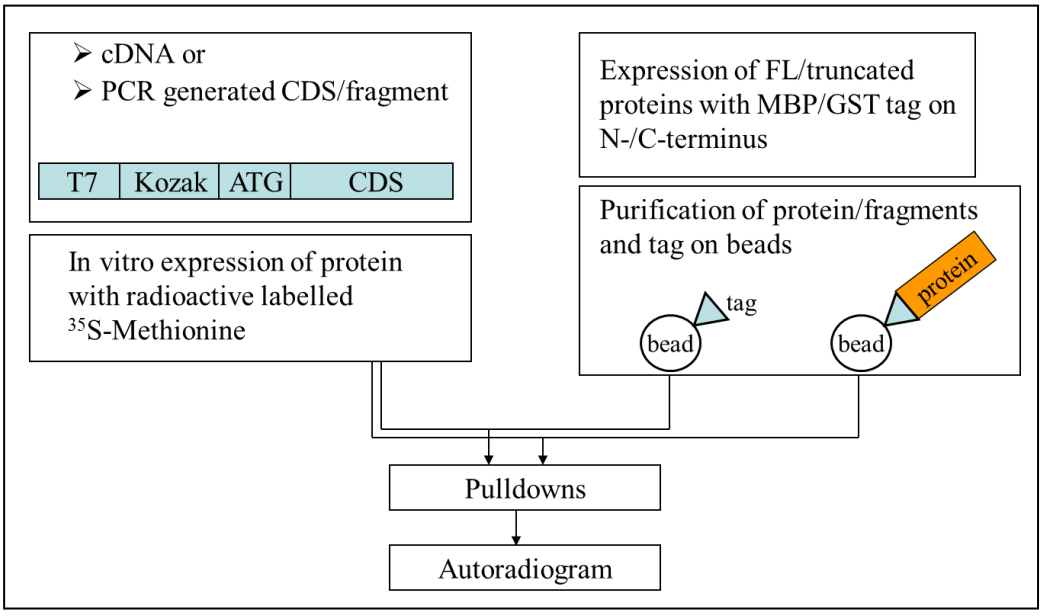

Figure 2-2 Schematic method of testing for direct protein interactions by *in vitro* binding assay. Two reagents were generated. Firstly, ^{35}S-Methionine labelled proteins from cDNA or PCR products by *in vitro* transcription-translation reaction (IVTT). And secondly, GST or MBP tagged protein, which was expressed and purified from *E. coli*, and stored on resin. For the binding assay or pulldown, two proteins were tested for their ability to interact directly. Therefore, one ^{35}S-Methionine labelled protein and one tagged protein to be tested for direct interaction were incubated together in binding buffer. After washes of the resin, it was subjected to SDS page and analysed by autoradiography.

Table 2-8 Summary of proteins that were generated by IVTT reaction. ^{35}S-Methionine labelled proteins used in this study (arranged as of their first appearance by chapter).

2.8.2 *In vitro* Plk4 kinase assay (MBP-Plk4-T172E phosphorylation assay using ^{32}P-γ-ATP)

To analyse if a protein is phosphorylated by active MBP-Plk4-T173E kinase a phosphorylation reactions was performed. The protein kinase or kinase dead (typically 4-10µg) was added to a reaction mix of 20-50µl, which contained Kinase Buffer (20mM Hepes, 100mM NaCl, 10mM MgCl2, 10mM MnCl2, 1mM DTT), 2.5mM ^{32}P-γ-ATP, 5-10µM cold ATP, tagged proteins bound to resin, ddH_2O. For non-radioactive kinase assays, 250µM cold ATP was used instead. The mix was incubated at 30°C for 45 minutes, followed by removal of the supernatant, adding 3x sample buffer containing 15%β-Mercaptoethanol and boiling of

the sample at 96°C for 5 minutes. Samples were subjected to SDS-PAGE for protein separation, followed by drying of the SDS-PAGE, direct exposure to hypersensitive film (Kodak BioMax MS film, 8222648) at -80°C and autoradiography.

2.8.3 *In vitro* binding assay of Sas6 with pre-treated Ana2

To study the *in vitro* interaction of Ana2 and Sas6 in chapter 4, it is necessary to pre-phosphorylate Ana2 with active Plk4 kinase; including the necessary controls. For this, 4-5µg of GST-Ana2/GST on resin were gently mixed in Kinase Buffer (20mM Na-HEPES pH 7.5, 100mM NaCl, 10mM $MgCl_2$, 10mM $MnCl_2$, 1mM DTT) with 250µM ATP; and ~4.5µg of active or kinase dead MBP-Plk4, and incubated at 30°C for 60 minutes, with a gentle mix every 3 to 5 minutes. After the incubation time, 400µl ice-cold Binding Buffer (50mM Na-HEPES pH 7.5, 100mM NaCl, 2mM $MgCl_2$, 1mM EGTA, 1mM DTT, 0.1%Triton-X100, 1.1 tablets of PhosStop/10ml BB, 1 tablet of PIC/35 ml BB, 100nM okadaic acid, 0.5mg/ml BSA) and ^{35}S-Methionine-labelled Sas6 were added to the reaction, and the samples were incubated for 2 hours at 15 rpm on a rotating wheel at 4°C. Adding PhosStop (Roche, 04906837001) gives a complete protection of proteins against a broad range of phosphatases according to manufacturer. The samples were then centrifuged at 1200 rpm for 3 minutes at 4°C, the supernatant was removed and the beads washed three times with 800µl Wash Buffer 1 (as Binding Buffer but without BSA) for 5 minutes at 4°C. The beads were then transferred into new chilled tubes and washed with 1ml Wash Buffer 1, followed by two washes with Wash Buffer 2 (same as WB1 but contains 10mM NaCl and 0.2%Triton-X100). Finally, 3x sample buffer containing 15%β-Mercaptoethanol were added and the samples boiled at 96°C for 5 minutes, followed by analysis on SDS-PAGE, drying of the gels and direct exposure to hypersensitive film (Kodak BioMax MS film, 8222648) at -80°C and autoradiography.

2.9 *Drosophila* cell culture and Human U2OS cell culture experiments

2.9.1 Cell cultures

Drosophila cell cultures were grown in Express Five SFM medium (Gibco^{TM}, Thermo Fisher Scientific, 10486-025) supplemented with 2mM L-glutamine (Gibco^{TM}, Thermo Fisher Scientific, 25030-024) and Pen Strep (Gibco^{TM}, Thermo Fisher Scientific, 15140-122). To generate stable cell lines, FuGENE HD Transfection Reagent (Promega, E2311) was used and procedures were performed as for transient transfection described in section 2.9.2, with the addition that 0.5µg of 'helper' plasmid carrying a Blasticidin resistance (pCoBlast) were added. The antibiotic selection started 48hours post-transfection with 20µg/ml Blasticidin. After 1 to 2 days the cells with antibiotic resistance start dividing, and once they are confluent, they were split and kept under 20µg/ml Blasticidin treatment for 6 to 8 passages until stably expression was reached. For localisation studies, *Drosophila* cell lines stably expressing Act5-myc-Dragon, poly-Ubiquitin-Dragon-GFP and poly-Ubiquitin-GFP-DragonΔ^{IM} were generated.

2.9.2 Co-IP experiment

Drosophila cells were transiently co-transfected with poly-Ubiquitin-GFP, poly-Ubiquitin-GFP-Dragon or poly-Ubiquitin-GFP-Dragon$^{\Delta IM}$ and Act5-6xmyc-Sas6, followed by GFP immunoprecipitated after 24-36 hours with 50nM okadaic acid (Calbiochem, 459620) in the lysis buffer, and subsequent Western Blot analysis. For the transient transfection $4.5x10^6$ cells were seeded in each well of a 6 well plate (Corning, 3516) and topped to 2ml with Express Five® SFM medium (Gibco^{TM}, Thermo Fisher Scientific, 10486-025), after 2 hours a mix of 3µg of vectors DNA in 100µl nuclease-free water and 15µl FuGENE® HD Transfection Reagent (Promega, E2311) was incubated for 15 minutes and then added

dropwise to the cells. The input samples of all three transient transfection confirmed the presence of Sas6 by anti-myc antibody staining (anti-myc 9E10, 1:6000, mouse), GFP/GFP-Dragon/GFP-Dragon$^{\Delta IM}$ by anti-GFP antibody staining (anti-GFP, 1:2000, rabbit) and as a control anti-α-tubulin (anti-α-tubulin DM1A, 1:2000, mouse). Secondary antibodies from Jackson ImmunoResearch were used at a 1:333 dilution (Table 2-5).

In collaboration with Dr. Lipinszki, *Drosophila* cells were transiently co-transfected with Actin5C-promoter-driven constructs encoding 3xFLAG-Ana2 (WT or 4A), Sas6-6xMyc or Plk4 (ND or NDKD) for 22 hours. Cells were treated with 25µM MG132 (Sigma-Aldrich, 133407-82-6) for 2.5hours before harvest. For the immunoprecipitation, the supernatants were mixed with anti-FLAGM2 magnetic beads (Sigma) for 3 hours at 4°C. After several washes proteins were eluted with 150 µg/ml 3xFLAG peptide, mixed with 3x sample buffer and subjected to SDS-PAGE followed by Western Blotting. Proteins were detected using the antibodies anti-Plk4 (1:2000, sheep), anti-FLAG (clone M2, 1:20,000, mouse), anti-myc (clone 9E10, 1:6000, mouse) and anti-α-tubulin (clone DM1A, 1:2000, mouse). Secondary antibodies from Jackson ImmunoResearch were used at a 1:333 dilution (Table 2-5).

2.9.3 RNAi – RNA interference

RNAi was performed using TransFast^{TM} transfection reagent (Promega, E2431). In the morning 1.5x10^{6} cells were transferred into wells of 6 well plates (Corning, 3516) with 2 to 4ml Express Five SFM medium (Gibco^{TM}, Thermo Fisher Scientific, 10486025) and transfection was performed 4 hours after. To prepare the transfection mix, 25µg of dsRNA were diluted in 1ml Express Five SFM medium, 20µl TransFast^{TM} transfection reagent was added and the whole mix was briefly vortexed, followed by 15 minutes incubation in which the complexes form. The medium was removed from the cells, which had attached to the bottom of the well, and the transfection mix was gently aspired in drops over the cells. The cells were incubated with the transfection mix for exactly 60 minutes at 25°C, after which 3ml

of Express Five SFM medium was added. The cells remained in the transfection-medium-mix for 2 or 4 days, after which 500,000 to 800,000 cells per ml culture were transferred onto ConA coated cover slides for methanol fixation and Histo-Immuno-Staining. Additionally, $1.5x10^6$ cells were transferred for a second round of knock down by RNAi and the above protocol was followed repeatedly for further rounds of knock down. In collaboration with Dr. Dzhindzhev, the *Drosophila* cell lines stably expressing pAct5-Ana2-WT, pAct5-Ana2-4A and pAct5-Ana2-4D were used in RNAi experiments. Additionally, RNAi experiments were performed on wild-type *Drosophila* cells and cells expressing poly-Ubiquitin-GFP-Dragon or poly-Ubiquitin-GFP-Dragon$^{\Delta IM}$.

Table 2-9 Summary of oligonucleotide primers used to generate dsRNA. Listed are the name of the primer, FW primer (FW), reverse primer (RV) and the primer sequence 5' to 3'. Red: T7 promoter sequence; CDS (coding sequence); UTR (untranslated region). For efficient dsRNA-based silencing of endogenous Ana2, a 225 bp-long hybrid DNA template containing a combination of T7 promoter sequence (red), Ana2's 5'UTR (black directly downstream of red T7 promoter sequence), 15 first nucleotides of the Ana2 CDS (blue), 15 last nucleotides of the Ana2 CDS (green) and Ana2's 3'UTR (black downstream of green), was generated by Overlap Extension PCR.

2.9.4 siRNA in U2OS cells

U2OS cells were maintained in growth medium DMEM (1X) + GlutaMAX^{TM}-I (Gibco® Thermo Fisher Scientific, 31966-021) with antibiotics and FBS (Gibco® Thermo Fisher Scientific, 10500) at 37°C, 5% CO_2, in a humidified incubator; and were passaged after trypsination from the flask with 0.05% Trypsin-EDTA (1X) (Gibco® Thermo Fisher Scientific, 25300-054). For the siRNA experiment (Figure 2-3), $1x10^5$ cells were plated in 2ml of growth medium without antibiotics per well of a 6-well plate (Corning, 3516) on day 1, to reach 30-50% confluence before starting the siRNA experiment. On day 2, firstly, 125µl Opti-MEM® Medium I (Gibco® Thermo Fisher Scientific, 31985-047) and 7.5µl Lipofectamine RNAiMAX reagent (invitrogen^{TM} Thermo Fisher Scientific, 13778-030), and secondly, 125µl Opti-MEM® Medium I (Gibco® Thermo Fisher Scientific, 31985-047) and 25pmol siRNA were each mixed and incubated for 3 minutes at RT. The diluted siRNA was then added to the diluted Lipofectamine RNAiMAX reagent, mixed by pipetting, and incubated for 10 minutes at RT. In the meantime, the medium of the U2OS cells was replaced with medium without antibiotics for 10 minutes, followed by adding the siRNA-lipid complex mix to the cells. On day 3 (24 hours after transfection), the media was replaced with fresh complete media and 4µM Aphidicolin and 1.5mM Hydroxyurea were added to induce S-phase arrest of the cells. The cells were then fixed to sterile and 1x PBS-washed cover slides 72 hours after siRNA transfection by cold methanol. GoRab was depleted via three target siRNAs (Silencer® Select siRNAs, 4392420, IDs: s40927, s40928, s40929), and GFP siRNA (Silencer® Select siRNA, Ambion^{TM}, Thermo Fisher scientific, AM4626) was used as a negative control. The cells were stained with anti-γ-tubulin (1:250, mouse, Sigma, T6557) and secondary antibody AlexaFluor® 594 donkey anti-mouse (1:333, Thermo Fisher Scientific, A21203) for centrosomes. When U2OS cells are blocked in S-phase by Aphidicolin and Hydroxyurea, DNA duplication and therefore cell division was prohibited, but centriole duplication still occurred as normal. This leads to an increase in the number of centrosomes within each cell under control conditions.

Table 2-10 Summary of the three GoRab Silencer® Select siRNAs. Listed are the sense and antisense strand siRNAs of the GoRab Silencer® used.

GoRab siRNA	sense	antisense
ID s40927	CAGAGACCAUGAAACUAAATT	UUUAGUUUCAUGGUCUCUGCC
ID s40928	CCAUGAUGGUCACAACAAUTT	AUUGUUGUGACCAUCAUGGGA
ID s40929	CAGCAAAGCUAGAUAUACATT	UGUAUAUCUAGCUUUGCUGCA

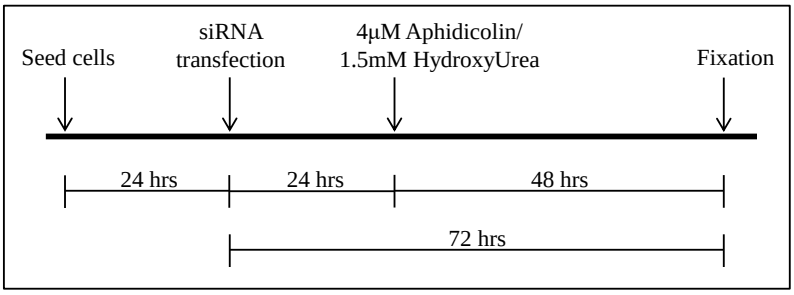

Figure 2-3 Time line of treatment of U2Os cells to study centrosome numbers after GFP and GoRab siRNA. U2Os cells were seeded at time point zero; siRNA transfection was performed 24 hours after; followed by arrest of cells in S-phase from 24 hours later by adding 4µM Aphidicolin and 1.5mM HydroxyUrea to the cell culture; and final fixation of cells 48 hours later.

2.9.5 Standard error and t-test

2.9.5.1 Standard error

The standard error was calculated for experiments were centrosomes were counted. Normally, three data points were generated; for all *Drosophila* cells 3 times 200 different cells were counted and for U2OS cells 3 times 100 different cells were counted. Initially, the Sample Standard Deviation was calculated by the square root of the Variance, which is the squared differences from the Mean divided by the 'number of data points minus 1', with the Mean being the average of the data points. From there the Standard Error was calculated by dividing the Standard Deviation by the square root of the 'number of data points'.

Data set: a, b, c

Mean: $M = (a+b+c) / n$ (n=population)

Sample Standard Deviation: $\sigma = \sqrt{[(a-M)^2 + (b-M)^2 + (c-M)^2) / (n-1)]}$

Standard Error: $SE = \sigma / \sqrt{n}$

2.9.5.2 t-test

For statistical analysis the paired t-test was used. It compares the population means of two correlated samples. Samples are classes as significant if $p<0.05$; and are categorised into statistically significant with $p<0.05$ (*) or $p<0.01$ (**) and statistically highly significant with $p<0.001$ (***).

2.10 Alignments and predictions

2.10.1 Protein sequence alignments

For the alignment of protein sequences to study their homology/orthology, protein sequences were acquired from http://www.flybase.org and alignments were performed with Clustal Omega [284] on http://www.ebi.ac.uk/Tools/msa/clustalo/.

2.10.2 Predicted secondary structure

For proteins of unknown secondary structure prediction softwares were used to indicate for potential secondary structure characteristics from protein sequences. Used were ‘psipred’ [285]

and ‘coils server’ [286] on http://bioinf.cs.ucl.ac.uk/psipred/ and http://www.ch.embnet.org/software/COILS_form.html respectively. The resulting ‘windows number’ in the latter were described in [286]; in short the higher the window number, the better the distinction between coiled-coil and other regions.

2.10.3 Phosphorylation sites prediction

Generic phosphorylation site predictions were generated with the NetPhos 2.0 server on http://www.cbs.dtu.dk/services/NetPhos/. It generates neural network predictions for serine, threonine and tyrosine phosphorylation sites as was published in [287]. Blotted are ‘Phosphorylation potential’ against the sequence position. A residue is predicted not to be phosphorylated if its ‘phosphorylation potential’ lies below the threshold.

Chapter 3

Physical interaction screen to elucidate protein interactions governing centriole duplication

3 Physical interaction screen to elucidate protein interactions governing centriole duplication

3.1 Introduction

Two genome wide dsRNAi screens in *Drosophila melanogaster* cell culture identified a total of eighteen proteins required for centriole duplication. Out of these, eleven, Asterless (Asl), Ana1, Ana2, Ana3, Bld10, Cep97, CP110, Plk4, Rcd4, Sas4 and Sas6 showed specific centriole localisation and are therefore likely to be directly involved in the process [131,288]. Many of these individual proteins are currently investigated and their role in centriole biogenesis is becoming clearer. However, still very little is known about the precise molecular mechanisms and the physical and functional interplay of these proteins in the pathway as a whole. It has been shown that the core proteins identified in *C. elegans* show similarities in their assembly and function in other systems, suggesting that the relationship between the centriole duplication proteins is conserved [90,289–292]. It is believed that Polo like kinase 4 (Plk4) is the functional homologue of Zyg-1 in insects and vertebrates, and that it is the key regulator of centriole duplication [83–85].

In this chapter I wished to study and identify the physical interactions between the proteins Asl, Ana1, Ana2, Ana3, Bld10, Cep97, CP110, Plk4, Rcd4, Sas4 and Sas6 and how they act together to control centriole duplication. For this purpose, I have generated antibodies against most of these proteins and I have performed *in vivo* and *in vitro* assays to test for direct and indirect interactions between these proteins. It is my aim to analyse the relationship of the proteins involved in the complex centriole duplication network. For this purpose, I firstly analysed mass spectrometry data of the ProteinA purifications generated in our group by Cunha-Ferreira, Dr. Dzhindzhev, Psternak, Schneider and Weiskopf and generated further purifications from *Drosophila* cells expressing proteins of the centriole duplication process (section 3.2.1), followed by an *in vitro* interaction screen to supplement

the *in vivo* findings by identifying direct protein-protein interactions (section 3.2.2) and applying the additional method of yeast-2-hybrid interaction (section 3.2.3).

3.2 Results

3.2.1 An *in vivo* protein interaction network of centriole duplication proteins designed from studies by ProteinA affinity purification

The tight regulation of centriole duplication is important for the maintenance of genomic stability, but only little is known about its molecular regulation. Therefore, my aim is to determine and map the physical interactions within the centriole duplication protein network using both *in vivo* and *in vitro* approaches. In this chapter I revisit ProteinA affinity purifications undertaken in our group; carry out and analyse additional ProteinA purifications of centriole duplication proteins; and create an interaction network considering the localisation of these proteins at the centrosome (Figure 3-1). To achieve single step affinity purifications, I expanded cell lines each expressing a centrosomal protein fused to ProteinA. I used IgG-coated resin to purify the expressed tagged protein and other endogenous proteins bound to it.

3.2.1.1 Plk4 – a master regulator forms complexes with the majority of proteins involved in centriolar duplication *in vivo*

Plk4 is described as the master kinase in centriole duplication and so it was of interest to identify its partners and substrates. Therefore, I focused on re-analysing previous ProteinA affinity purifications of ProteinA-tagged Plk4 purified from cultured cells and analysed by mass spectrometry, performed by K. Weiskopf and Dr. Dzhindzhev (complete lists in Appendix A). Of the possible Plk4 interactors, Asterless was the most striking showing a high Mascot score when co-purified with Plk4, indicating that peptides derived from Asterless were abundant in the purification (Table 3-1A). This is significant because genetic analysis shows that overexpression or depletion of Asterless results in similar phenotypes to

overexpression and depletion of Plk4 [92]. In reciprocal purifications of Asterless tagged with ProteinA, Plk4 was also found as an interacting partner (Table 3-1B). Asterless was shown to recruit Plk4 to the centriole [92]. In addition to Plk4, Sas4 was also identified as a binding partner of Asterless. This suggests that Asterless is required for centriole duplication to form a scaffold that binds Plk4 and Sas4 [92,293,294]. Such a scaffold would bring Plk4 close to Sas4 or other centriolar proteins, to allow for their phosphorylation by Plk4. The purifications of Plk4 tagged to ProteinA also identified centriolar proteins (Table 3-1 A). Components of zone 1: Bld10 and Ana2; components of zone 2: Ana1, Sas4 and Spd2; components of zone 3: Asterless and D-Plp; components of zone 4: Cnn and Spd2, and in zone 5: CP110. The localisation of Ana3, also found in the purification, remains unknown in the centrosome (Figure 3-1, locations according to [24,30]). The localisation of these proteins might be important for the characterisation of the precise role of Plk4 at the centrosome and in identifying its substrates. As Asterless is known to recruit Plk4 directly, I also re-analysed affinity purifications of Asterless from cultured *Drosophila* cells, to identify potential additional interactors of the Asterless scaffold [92]. This identified Ana1, Bld10, D-Plp, Sas4, Spd2 and Plk4 (Table 3-1B). In summary, these purifications identify the proteins Ana1, Bld10, D-Plp, Sas4 and Spd2 in complex with Plk4 and Asterless. On the other hand, only Ana2, Ana3, Cnn and CP110 are specific in complex with Plk4 but not with Asterless.

Table 3-1 Mass spectrometry data from purifications of Plk4 (A) and Asterless (B) confirms centriole duplication proteins. ProteinA tagged Plk4 and Asterless were expressed and purified from *Drosophila* cell culture, followed by gel-free mass spectrometry analysis. The tables show the Mascot 'score' and 'number of peptides' of each according centriolar duplication and maturation protein identified in the purification data. OA, okadaic acid. MG132 treatment to inhibit proteasomal degradation. Complete lists in Appendix A.

3.2.1.2 *In vivo* studies of the centriole duplication proteins Ana2, Asterless, Cep97, CP110, Plk4, Rcd4 and Sas4 suggests a protein network

Additional ProteinA affinity purifications and mass spectrometry studies were then performed with Ana1, Ana2, Bld10, Cep97, CP110, Rcd4, Sas4 and Sas6, to search for candidates for their interacting proteins. The affinity purified complexes were analysed via gel free mass spectrometry. In the majority of cases, proteins were tagged with ProteinA on both their N- and C-terminus, to exclude possible interference of the affinity tag with binding. The affinity purifications of Ana1, Bld10 and Sas6 tagged to ProteinA did not identify any candidates involved in centriole duplication. However, the following proteins were found complexed to other centriole proteins: 1.) Ana2 purification identified Ana1, Plk4, Polo and Sas4; 2.) Sas4 purification identified Ana2, D-Plp and Polo; 3.) Rcd4 purification identified Ana2 and Ana3; 4.) Cep97 purification identified Ana2, CP110, D-Plp and Polo; and 5.) CP110 purification identified Cep97, Cnn, D-Plp and Polo (Table 3-2).

Interestingly, Ana2 was identified in complex with Sas4 and Plk4, and in the reciprocal ProteinA purifications the proteins Sas4 and Plk4 were identified in complex with Ana2, which strengthens the confidence of a potential interaction of Ana2 with Sas4 and Plk4 (Table 3-1, Table 3-2).

It is also noticeable that treatment of the *Drosophila* cells expressing Sas4 with okadaic acid seems to stabilise Polo in complex, as it was not identified when the cells were untreated. Thus Polo's association with Sas4 might be phospho-dependent.

Similarly, only when cultured *Drosophila* cells expressing Cep97 were treated with okadaic acid, was CP110 found in the complex. This suggests that CP110 complexes with Cep97 in a phosphorylation-dependent manner.

Based upon these interactions I have constructed an interaction network between these proteins positioned at their known sites within the 3D structure of the centrioles as described by 3D-SIM (Figure 3-1) [24,30].

Table 3-2 Mass spectrometry data of centriole duplication proteins purified from *Drosophila* cell culture expressing ProteinA tagged Ana2, Sas4, Rcd4, Cep97 and CP110. Shown are the Mascot 'score' and 'number of peptides' identified of centriolar duplication and maturation proteins that were analysed in the purifications by mass spectrometry. OA, okadaic acid. Figure 3-1 *In vivo* connections of centriolar duplication and maturation proteins and their localisation within the centrosome. (mass spectrometry data from Cunha-Ferreira, Dzhindzhev, Psternak, Schneider and Weiskopf; localisation studies from Fu [24,30]). Localisation of Ana3 and Rcd4 is unknown. Polo and Spd2 are localised in zone 2 and 4. Black lines connect proteins involved in centriole duplication. Blue lines connect to proteins involved in centriole maturation. Asl interaction with Plk4 and Sas4 was shown in [92].

As the localisation of Rcd4 within the centrosome had not been described, I depleted the protein by RNAi in cultured *Drosophila* cells. Cells were fixed and stained to reveal the centrosome marker D-Plp. This clearly showed that the knock down of Rcd4 over a 16 day interval resulted in a reduction of the number of centrosomes (Figure 3-2; 52.5% +/-2.5% of cells lost their centrosomes). The effect of Rcd4 depletion was less efficient than the positive control, depletion of Asterless, which causes loss of almost all centrosomes after 16 days of RNAi (90.8% +/-0.3%) but significantly greater than control GST RNAi (9.6% +/-1.8%). This confirms the findings of Dobbelaere *et al.* [131] that Rcd4 is required for centriole duplication.

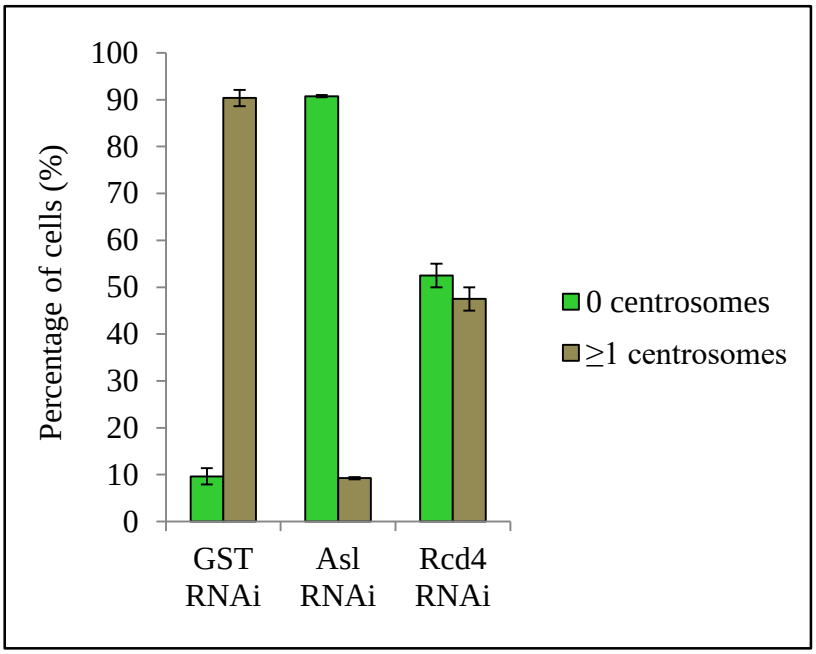

Figure 3-2 Effect of Rcd4 depletion on centrosome numbers in *Drosophila* cell culture. Rcd4 RNAi, Asterless RNAi (positive control) and GST RNAi (negative control) for 16 days with knock down every 4 days. High loss of centrosomes after Rcd4 and Asterless depletion. 3x200 cells; error bars represent standard error.

3.2.2 *In vitro* protein interaction assays confirm and expand interactions between centriole duplication proteins identified *in vivo*

To attempt to determine which of the above interactions might be direct I chose to carry out *in vitro* interaction assays. To this end, I asked whether the eleven centriolar duplication proteins (Ana1, Ana2, Ana3, Asl, Bld10, Cep97, CP110, Rcd4, Sas4, Sas6 and Plk4) and the pericentriolar proteins Cnn, D-Plp, Polo and Spd2, involved in the centrosome maturation process, would interact. For this study, I generated one putative partner that was ^{35}S-Methionine-labelled by coupled transcription-translation reactions and the other partner expressed as a fusion in *E. coli* (section 2.8.1, section 2.5.1). The binding complex was subjected to SDS-PAGE, followed by autoradiography. I simultaneously analysed a negative control (the tag alone bound to resin) and 1% input of the total radioactively labelled protein. I successfully expressed and purified eight tagged full length proteins (Ana2, Asl, Bld10,

Cep97, Rcd4, Sas4, Sas6 and Plk4), and two fragments of CP110 (aa1-400 and aa360-570) for which the pENTR clones were kindly shared with me by Dr. Fu. I was not successful in my cloning strategy for Ana3. Moreover Ana1 and CP110 (aa571-666) could not be expressed successfully. I compared the autoradiographic signals for the protein interactions with the input and the corresponding negative control, and categorised the strength of the signal as: no interaction (-), weak interaction (+), interaction (++) and strong interaction (+++), with “d” indicating, that the strongest signal was observed as degraded protein (individual autoradiographic signals in Appendix B). I excluded tagged Sas6 and tagged Bld10 from the analyses, as these proteins exhibited strong non-specific binding to other proteins, most likely due to aberrant folding of Sas6 and Bld10. I was still able to analyse the reciprocal experiment following the binding properties of ^{35}S-Methionine labelled Sas6 and Bld10. All interactions are summarised in Table 3-3 [24,30]. The strongest direct protein interactions observed *in vitro* (+++) are highlighted in blue in Table 3-3. These are also indicated in relation to the localisation of the potential partner proteins within the centrosome in Figure 3-3; where black connecting lines highlight protein interactions that were also found *in vivo* (section 3.2.1); red connecting lines highlight strong protein interactions identified only *in vitro*. Good *in vitro* protein interactions (++) that verify *in vivo* protein interactions are highlighted in green in Figure 3-3.

In summary, the *in vitro* analyses of direct protein interactions suggest that some proteins found in complex *in vivo* correspond to direct interactions, namely Ana2 with Sas4, Ana2 with Plk4, CP110 with Polo, Asl with Plk4, Asl with Spd2 as well as Asl with Sas4 [92]. Additional interactions were only identified *in vitro*. These include CP110, which localises in the cap of the centriole (zone 5) that interacts strongly with Sas4 (zone 2) and vice versa *in vitro*. Additionally, CP110 is also linked to Ana3 (zone 1), Sas6 (zone 1) and Ana1 (mainly zone 2) by an *in vitro* interaction; and Sas4 (zone 2) is linked to Ana1 (mainly zone 2) and Rcd4 by direct *in vitro* interaction. Figure 3-3 also highlights potential protein interactions in green that were identified as a good interaction *in vitro* (++) and were also found associated in complex *in vivo*. These include interactions of Plk4 with Ana3, Bld10, CP110, D-Plp and Sas4; Ana2 with Cep97, Polo and Rcd4; Sas4 with D-Plp, Plk4 and Polo; CP110 with Cep97

and Cnn; Rcd4 with Ana3; and Cep97 with Ana2, Polo and CP110 (Table 3-1, Table 3-2, Figure 3-3). The assays also revealed strong interactions of Ana2, Rcd4 and CP110 with themselves but should be studied more carefully in future.

Table 3-3 Direct interaction levels of centriolar proteins using *in vitro* binding assays. Binding assays of radioactively labelled protein and tagged full length protein. Signals were categorised into no interaction (-), weak interaction (+), good interaction (++) and strong interaction (+++, blue background), with "d" indicating degraded protein size. The zones relate to the different layers of centrioles as described in [24,30]; ? indicates unknown protein localisation in the centrosome. GST-CP110 1/3 (aa1-400), GST-CP110 2/3 (aa360-570), D-Plp-N (aa1-1603), D-Plp-C (aa1604-2727). Individual autoradiographic signals in Appendix B.

3.2.3 Confirmatory studies using the Yeast-2-Hybrid Assay

The *in vivo* and *in vitro* analyses of complexes that I have described each have their advantages and disadvantages. The advantages of the *in vitro* method are its high sensitivity and its detection of direct interactions. On the other hand, the *in vivo* method detects proteins which form complexes between proteins that are correctly folded due to post-translational modifications. The *in vitro* method has the drawback that some protein interactions could only be observed in one direction but not reciprocally; for example: bacterially expressed Plk4 interacted well with ^{35}S-Methionine-labelled Rcd4 whereas bacterially expressed Rcd4 did not interact with ^{35}S-Methionine-labelled Plk4. The *in vivo*

method is much less sensitive than in the *in vitro* approach. Thus certain interactions could only be detected *in vitro* but were not represented in complexes present *in vivo*. This could represent inaccessibility of a complex or formation of a complex at a specific time during the centriole duplication cycle. The yeast-2-hybrid system combines elements of the *in vitro* and *in vivo* methods, as it tests for direct protein-protein interactions but is performed within a eukaryotic cell and allows for post-translational protein modifications. I therefore applied the yeast-2-hybrid system in an attempt to confirm or deny protein interactions that were detected in only one of the previously applied methods. Methodically, the yeast-2-hybrid system is based on the activation of the GAL promotor by its transcription factor, which is split into a Binding Domain (BD) and an Activation Domain (AD). Each protein is tagged with these domains individually. Hence, when two proteins interact directly, they bring the AD and BD together, forming the functional transcription factor and activating the GAL4 transcription (section 2.7). The use of X-α-GAL gives a visual indication (colonies turn blue after up to 6 days at 30°C when a protein interaction occurs), if the two proteins interact directly and activate the GAL promotor. For the yeast-2-hybrid analysis, I generated 11 proteins in pGAD424 tagged with the GAL4 AD (Ana2, Asl, Bld10, Cep97, CP110, Plk4, Rcd4, Sas4, Sas6, Polo and Spd2), five proteins in pBGT9 tagged with the GAL4 BD (Ana2, Bld10, CP110, Sas4 and Sas6), two negative controls (AD-only, BD-only), and as positive controls I used BD-tagged Nnf1a and AD-tagged Mis12, and vice versa. Mis12 and Nnf1a are two interacting proteins in the Mis12 complex of the kinetochore [295]. All constructs were tested for autoactivation of the GAL promotor, of which only BD-Asl tested positive for autoactivation. Hence, only AD-Asl was used for interaction studies of Asterless.

My hybrid screen focused on centriolar proteins that localise to zone 1 and zone 2 of the centrosome and identified protein-protein interactions (highlighted in blue in Table 3-4). These confirm protein interactions found *in vitro* and in *in vivo* complexes (***), confirm protein interactions only found *in vitro* (a equals strong interaction (+++); b equals good interaction (++)), and suggest additional protein interactions (blue filled cells only). These interactions are summarised in relation to their localisation within the centrosome in Figure 3-4. Interestingly, the yeast-2-hybrid method confirms the interactions of Ana2 with Plk4,

Sas4 and Polo, as previously described by the *in vitro* and *in vivo* tests (section 3.2.1, section 3.2.2). These are highlighted by black connection lines in Figure 3-4. The yeast-2-hybrid also confirms strong protein interactions (+++) observed *in vitro* of CP110 and Sas6, and the strong interaction of CP110 and Ana2 with themselves (marked 'a' in Table 3-4), and additionally confirming some good protein interactions observed *in vitro* (++) of Sas4 with itself, Sas6 with Sas4, and Spd2 with Ana2, Cep97 and CP110 (marked 'b' in Figure 3-4). The yeast-2-hybrid method also identified additional protein interactions which were not described in section 3.2.1 and 3.2.2. These include Sas6 with Ana2, Ana2 with Bld10, Sas6 with itself, Sas6 with Polo and Spd2, and Bld10 with Spd2 which are highlighted in orange in Figure 3-4.

Table 3-4 Confirmation of protein interactions found *in vivo* and/or *in vitro* applying the yeast-2-hybrid system. pGBT9 containing the GAL4-BD. pGAD424 containing the GAL4-AD. Blue highlighted boxes: observed protein interactions applying the yeast-2-hybrid method. White boxes: no protein interactions observed by yeast-2-hybrid. Additional symbols *** for interactions previously detected *in vivo* and *in vitro* (as good (++) or strong (+++) interactions); 'a' for interactions previously detected as strong interactions *in vitro* only (+++); 'b' for interactions previously detected as good interactions *in vitro* only (++).

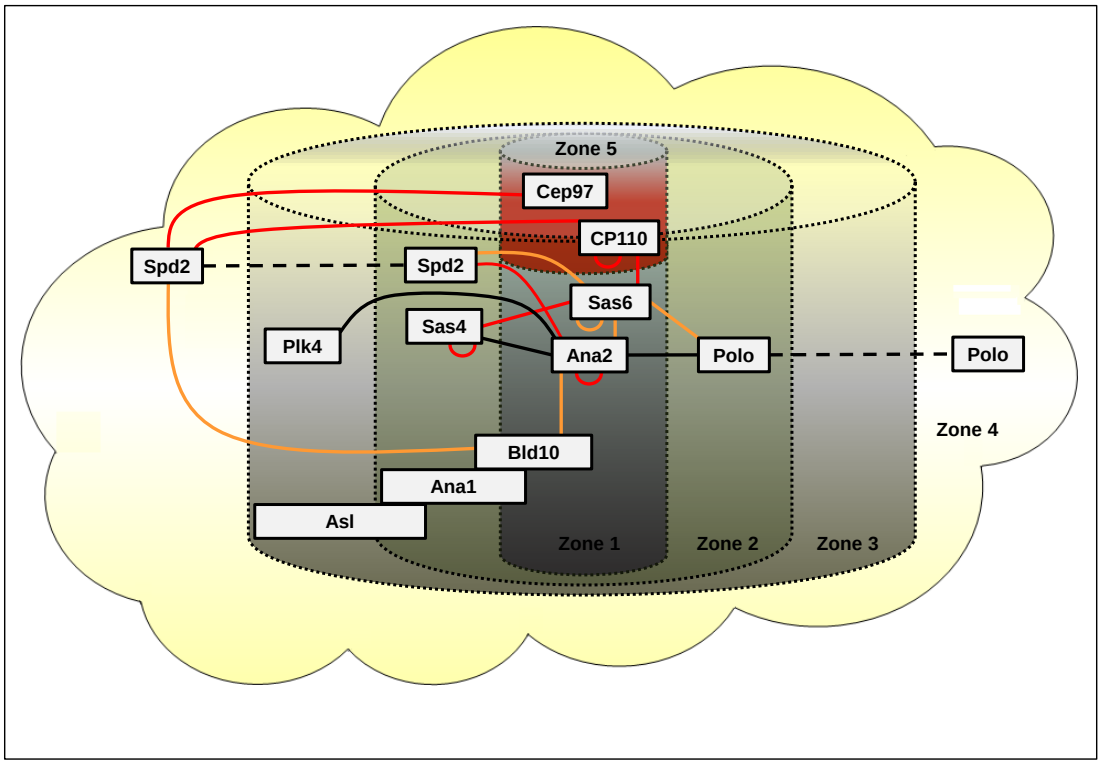

Figure 3-4 Diagram summarising the protein interactions detected by yeast-2-hybrid and confirming protein interactions identified by *in vivo* and *in vitro* methods. Black lines confirm proteins found in complex *in vivo* and as direct protein interactions *in vitro* (strong and good protein interactions). Red lines confirm interactions previously detected by strong or good *in vitro* interaction only. Orange lines indicate protein interactions newly detected by yeast-2-hybrid or previously identified as a (very) weak *in vitro* interaction.

3.3 Discussion

The studies I report in this chapter suggest that Plk4, master regulator of centriole duplication, directly or indirectly interacts with and regulates proteins localised in complex present *in vivo* within every zone of the centrosome. Additional ProteinA affinity purifications indicate a complex network of interacting proteins that participate in centriole duplication and centrosome maturation proteins (Figure 3-1). The *in vitro* interaction studies I carried out to identify direct protein-protein interactions gave some suggestions on functionally important interactions. It was previously shown that Asterless functions as a scaffold to recruit Plk4 and Sas4 to the daughter centriole, with the Asterless/Plk4 interaction being necessary for centriole duplication [92]. Significantly, Plk4 localises in the outer layer of the centrosome (zone 3) and Sas4 localises in the inner layer (zone 2), which goes in line with the recent discovery that their interacting protein partner Asterless localises mainly to zone 3 but also partially to zone 2 [30]. I was able to demonstrate these interactions as direct protein interactions *in vitro*. Plk4 interacts strongly with Asterless and vice versa; additionally, Asterless interacts with Sas4 and vice versa in the performed binding assays (Table 3-3). Hence, the *in vitro* method appears reproducible and reliable, and sheds further light on the finding of interactions *in vivo*. As seen in Figure 3-1, Plk4's partners are present in every zone of the centrosome, implying potentially diverse regulatory roles. Alternatively the large number of centriole duplication proteins purifying with Plk4 could indicate direct or indirect interactions occurring in the cytoplasm prior to incorporation into the centriole; for example Bld10 localises to zone 1 in the centriole but its interaction with Plk4 has not previously been described. At the time these *in vivo* analyses were carried out, neither direct substrates of Plk4 nor the timing of their interactions were known. Recently, it was discovered that Ana2 is a substrate of Plk4 and must be phosphorylated by Plk4 to allow for interaction and recruitment of Sas6 to the site of procentriole formation (Chapter 4) [296]. Significantly, Ana2 and Plk4 were detected in the reciprocal *in vivo* purifications (Table 3-1, Table 3-2) but with a low Mascot score and a low 'number of peptides'. The reason for this is not clear but could be explained if the interactions of the kinase with its substrates are only transitory. The

interaction of Plk4 and Ana2 was confirmed as a direct interaction *in vitro* and additionally confirmed by the yeast-2-hybrid method.

Plk4 localises in zone 3 of the centrosome together with D-Plp and Asterless. The high Mascot scores of D-Plp in the Plk4 and Asterless purifications suggest a robust complex of these proteins. D-Plp is found predominantly on the mother centriole for most of the duplication cycle. D-Plp's C-terminus is localised at the centriole wall, from where it radiates outwards into the matrix, D-Plp could be a possible candidate for the recruitment of Asterless to the centriole [24,27]. Although recently it was shown that Bld10, Ana1 and Asterless are recruited sequentially in the centriole-to-centrosome conversion, that Asterless and Ana1 interact with each other, and that depletion of Ana1 leads to failure of Asterless and D-Plp localisation to the metaphase daughter centriole [30]. This suggests that D-Plp might be recruited to the centriole upstream of Asterless. Additionally, D-Plp has been shown to interact with Sas4 during PCM recruitment but its role in centriole duplication still needs to be investigated further [137,297].

On the other hand, in *C. elegans*, it was shown that Sas4 is recruited to the centriole by Sas5 (the Ana2 homologue) [53,91]. In accord with this I observed an interaction of Sas4 and Ana2 *in vivo*, *in vitro* and by yeast-2-hybrid, suggesting the possibility of a similar role of the Sas4/Ana2 interaction in *Drosophila*.

Of additional interest is the observation that Sas4 interacts directly with Cep97, CP110 and D-Plp *in vitro* but I identified only Cep97 and CP110 in complex with D-Plp *in vivo*. Sas4 has been associated with the process of PCM recruitment [11,20,25]. And a link to the cartwheel is supported by Sas4's interaction with proteins in zone 1 (Ana2) and zone 3 (Asterless, D-Plp) of the centrosome. In human cell culture, overexpression of CPAP (Sas4 homologue) leads to increased centriole length by enhanced accumulation of centriolar tubulin [38–40]. Elongated centrioles have also been observed after depletion of CP110, suggesting that CPAP and CP110 have antagonistic functions during centriole elongation and control centriole length [39], and Cep97 and CP110 function in cilia formation and length regulation [79,81]. On the other hand, in *Drosophila*, CP110 seems to restrict centriole length in a microtubule-depolymerising kinesin-like protein 10A (KLP10A) dependent manner [80,82].

Spd2 was also found in complex with Plk4 and Asterless, a finding of interest, as Spd2 exhibits a dual-localisation in zone 2 of the centrosome during interphase and mitosis, but additionally localises in zone 4 (PCM) after the onset of mitosis. This is also the case for Polo, which localises in zone 2 of the centrosome during interphase but also largely localises to zone 4 from metaphase onwards, where it is required for PCM recruitment [24]. In contrast to Spd2, Polo was also identified in complex with centriole duplication proteins that are in the core of the centrosome in zone 1, 2 and 5 (Ana2; Sas4; and Cep97 and CP110 respectively). This was confirmed by *in vitro* interaction studies, and the yeast-2-hybrid method confirmed the Polo and Ana2 interaction. Polo was only identified in the Sas4 purification when the cells were treated with okadaic acid, suggesting a potential phosphorylation-dependency of the Sas4/Polo interaction.

The connection between Ana3 and Rcd4 is of interest, as pilot experiments have linked Rcd4 to zone 1 or zone 5 by structured illumination microscopy on cultured cells expressing GFP-tagged Rcd4 (data not shown; cell lines by Mr Meghini; microscopy by Dr. Tzolovsky). The initial data suggests that Rcd4 recruitment to the centriole starts in interphase and reaches similar protein levels as Sas6 in metaphase (data not shown). Further studies will conclude the localisation of Rcd4 and give suggestions for Ana3 localisation.

The yeast-2-hybrid method confirms *in vitro* findings of potential self-interactions of Ana2, CP110 and Sas4. This accounts with the homodimerisation potential of Sas6 with itself, which has since been described in structural studies but was not detected in previous *in vivo* nor *in vitro* analyses [63,69]. Most interestingly, the interaction of Ana2/Sas6 was found using yeast-2-hybrid but not by *in vivo* and *in vitro* approaches. Significantly, at the time of the experiments, it was known that the interaction of *C. elegans* Sas5 and Sas6 is necessary in centriole duplication [53] but we showed only later that they also interact in *Drosophila* but in a manner dependent on Plk4 phosphorylation of Ana2 (Chapter 4) [296]. This was also confirmed in human cell culture for STIL and Sas6 [95,299,300]. The interaction of Ana2 and Bld10 was only detected by yeast-2-hybrid but not by *in vivo* or *in vitro* binding tests. Both proteins localise to zone 1 of the centriole and could possibly contribute to the formation or stability of the 9-fold

symmetry of the cartwheel/centriole. Further studies need to confirm or dismiss the interaction of Bld10 and Ana2.

In conclusion, the studies I describe in this chapter have analysed proteins of centriole duplication and maturation that form complexes *in vivo* and were shown to interact directly by *in vitro* binding assays. Proteins that were found in complexes *in vivo* but did not interact *in vitro* might be connected indirectly. On the other hand, strong interactions found *in vitro* but that were not reflected in *in vivo* complexes could represent transient interactions in the centriole duplication cycle. The additional application of the yeast-2-hybrid method combines the advantages of testing for direct protein interactions in a system that allows for post-translational modifications. It confirmed protein interactions that were identified both *in vivo* and *in vitro*, and also protein interactions that were identified by the more sensitive *in vitro* approach only.

In summary, the application of *in vivo*, *in vitro* and yeast-2-hybrid methods in a screen to identify interactions of centriole duplication proteins has proven to be a guide to further studies rather than providing totally reliable conclusions. Each method in itself can be a strong and reliable method but needs to be accompanied by additional and more specific evidence of functional interaction to be conclusive.

Chapter 4

Interaction of Ana2 and Sas6 – Mediated by Plk4 phosphorylation of Ana2 and enabling procentriole formation

4 Interaction of Ana2 and Sas6 – Mediated by Plk4 phosphorylation of Ana2 and enabling procentriole formation

4.1 Introduction

Five proteins have been described to be essential in the centriole duplication pathway in *C. elegans*; Spd2, Zyg-1, Sas6, Sas5 and Sas4 [16–20,22,23,72,301]. My attempt to define the direct protein interactions of the *Drosophila* homologues and further centriole duplication proteins (Chapter 3) did not give the expected understanding how these *Drosophila* centriole duplication proteins interact with each other. Thus they gave little insight into molecular mechanisms underlying centriole duplication. The similarities of the core proteins identified in *C. elegans* in their assembly and function in other systems indicates that interactions between centriole duplication proteins are conserved [90,289–292]. The *Drosophila* proteins Ana2 and Sas6 were of particular interest and here I focus on their interactions. Their *C. elegans* homologues, Sas5 and Sas6, are recruited together to the procentriole, after Spd2 mediates recruitment of Zyg-1 [114,302]. However, how *Drosophila* Ana2 and Sas6 might interact was not clear. The substrates of the master kinase of centriole duplication Plk4 were also unknown. As in *C. elegans*, Zyg-1 is recruited upstream of the Sas5-Sas6 complex, I asked whether Ana2 and Sas6 interact, if they are substrates of the Plk4 kinase and function together in the centriole duplication process.

4.2 Results

4.2.1 Plk4 directly interacts with and phosphorylates Ana2 but not the centriole cartwheel protein Sas6

The recruitment of centriole duplication proteins is well described in *C. elegans* with Spd2 recruiting Zyg-1, the Plk4 homologue, followed by recruitment of Sas5 and Sas6 to the nascent procentriole, and recruitment of Sas4 for microtubules assembly [53,91]. In *Drosophila melanogaster*, the protein recruitment hierarchy of centriole biogenesis is similar to *C. elegans* but with some differences. Rather than Spd2, Asterless (Asl), a protein not present in *C. elegans*, recruits Plk4, the Zyg-1 homologue to the procentriole [92]. In human cells, both Cep152 and Cep192, the homologues of Asterless and Spd2 respectively cooperate in Plk4-recruitment in centriole biogenesis [93]. One question still remaining is what ensures the timely and functional recruitment of the *Drosophila* homologues of Sas5 (Ana2), Sas6 and Sas4 to the pro-centriole, especially in the light of Plk4s' characterisation as the master kinase for centriole duplication. We know that Plk4 is recruited to the centriole by Asterless and that Asterless interacts with Sas4 [92]. But despite this knowledge, we do not know the critical substrates that are phosphorylated by Plk4 during centriole duplication.

4.2.1.1 Ana2 and Plk4 interact *in vitro* but neither shows binding with Sas6

To address the above questions, I first attempted to determine which centriole proteins interact with each other during centriole duplication in *Drosophila*. Therefore, I performed an *in vitro* interaction screen in which I expressed tagged centriole duplication proteins (with MBP or GST) in *E. coli* and purified them on resins to determine whether they would interact with individual ^{35}S-Methionine-labelled centriole duplication proteins produced in an *in vitro*

transcription-translation system. This allowed me to directly test whether two proteins bind each other by combining a) protein bound to resin with b) ^{35}S-Methionine-labelled protein in an *in vitro* interaction assay (section 2.8.1). The resin was then washed and subjected to SDS-PAGE, directly followed by protein transfer onto nitrocellulose membrane and autoradiography at -80°C. Such experiments revealed that Plk4 and Ana2 interact directly with each other *in vitro* (Figure 4-1). The autoradiogram in Figure 4-1A shows 1% input of ^{35}S-Methionine labelled Ana2 (lane 1) and the analysed interaction complexes of MBP and MBP-Plk4 with ^{35}S-Methionine-labelled Ana2 (lane 2 and 3 respectively). ^{35}S-Methionine-labelled Ana2 does not interact with MBP alone. Therefore, the observed signal with MBP-Plk4 is due to direct interaction of Ana2 with Plk4. The reciprocal assay is shown in Figure 4-1B and confirms the observations from Figure 4-1A. The autoradiogram in Figure 4-1B shows 1% input of ^{35}S-Methionine-labelled Plk4 (lane 1) and the interaction complexes of GST and GST-Ana2 with ^{35}S-Methionine-labelled Plk4 (lane 2 and 3 respectively). Plk4 does not interact with GST but the detected signal of ^{35}S-Methionine-labelled Plk4 with GST-Ana2 confirms that Plk4 directly interacts with Ana2 *in vitro*.

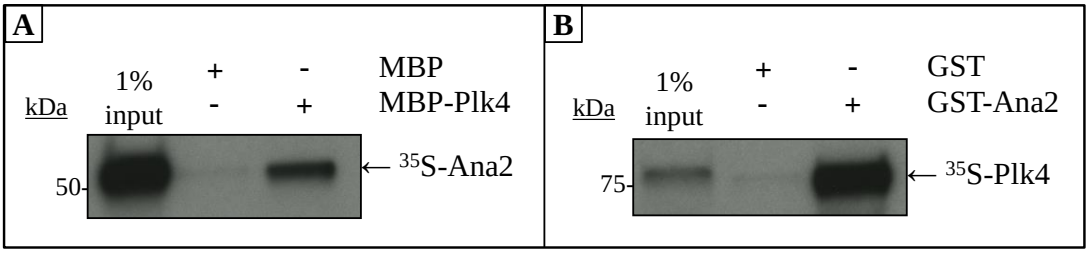

Figure 4-1 Ana2 and Plk4 protein interact directly *in vitro*. (A) MBP and MBP-Plk4 immobilised on resin were incubated with ^{35}S-Methionine-labelled Ana2 in an *in vitro* binding assay, subjected to SDS-PAGE and autoradiography. (B) GST and GST-Ana2 immobilised on resin were incubated with ^{35}S-Methionine-labelled Plk4 *in vitro*, subjected to SDS-PAGE and autoradiography. Autoradiograms show that Ana2 is found in complex with Plk4 (A) and Plk4 is found in complex with Ana2 (B).

The *in vitro* interaction assays shown in Figure 4-1 show that Plk4 and Ana2 interact directly with each other. It is known from *C. elegans*, that Sas5 and Sas6 are recruited to the

centriole after Zyg-1 recruitment [53,91], with Ana2 and Sas6 being the respective homologues in *Drosophila*. This raises the question of whether *Drosophila* Sas6 can interact with Plk4 or Ana2. To address this, I applied the direct binding assay as described above using ^{35}S-Methionine-labelled Sas6 and MBP or MBP-Plk4 (Figure 4-2 A) and with GST or GST-Ana2 (Figure 4-2 B). I found no direct interaction of Sas6 with either of the two proteins, either with Plk4 or the negative control MBP (Figure 4-2A) or Ana2 or the negative control GST (Figure 4-2B).

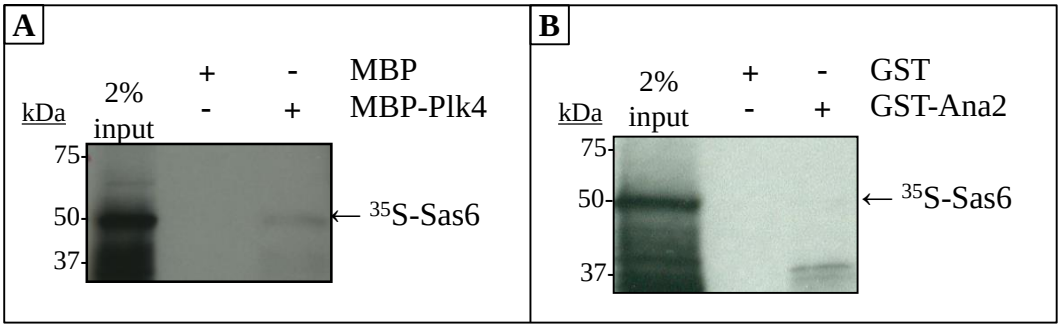

Figure 4-2 Plk4 and Ana2 proteins do not bind Sas6 directly *in vitro*. ^{35}S-Methionine-labelled Sas6 was incubated with MBP and MBP-Plk4 bound to resin (A) and GST and GST-Ana2 bound to resin (B). 2% ^{35}S-Methionine-labelled Sas6, as input, and the resin complexes were subjected to SDS-PAGE and autoradiography. The autoradiograms show that Sas6 was not associated with Plk4 (A) nor with Ana2 (B).

4.2.1.2 Plk4 phosphorylates itself and Ana2 *in vitro* but not Sas6

Initially, I expressed and purified MBP-Plk4-T172E-K43M and MBP-Plk4-T172E, the N-terminal MBP-tagged kinase dead and active form of Plk4 respectively. The expression constructs for MBP-Plk4-T172E-K43M and MBP-Plk4-T172E were generated by Dr. Dzhindzhev. MBP-Plk4-T172E carries a mutation at aa172 from T (Threonine) to E (Gutamic acid), located in the T-loop within the cryptic polo box of Plk4. MBP-Plk4-T172E-K43M carries an additional mutation at aa43 from K (Lysine) to M (Methionine), which is located in the kinase domain of Plk4 and corresponds to the kinase dead Plk4 version.

Plk4 is known to auto-phosphorylate in a self-regulatory fashion [107,109]. This auto-phosphorylation is also observed with MBP-Plk4, as a bandshift of the MBP-Plk4 protein can be observed when the protein is analysed on SDS-PAGE. To test if the purified batch of MBP-Plk4-T172E protein is an active Plk4 form and has phosphorylation ability, I incubated MBP-Plk4-T172E with lambda-phosphatase buffer and analysed its mobility on a SDS-PAGE in comparison to a) the active version treated with lambda phosphatase and b) the kinase dead version MBP-Plk4-T172E-K43M (Figure 4-3). A protein shift can be observed with MBP-Plk4-T172E treated with lambda phosphatase (lane 4) and MBP-Plk4-T172E-K43M (lane 1), confirming that MBP-Plk4-T172E is active and auto-phosphorylates. MBP-Plk4-T172E treated with lambda phosphatase (lane 4) has a similar mobility to kinase dead MBP-Plk4-T172E-K43M (lane 1). Thus the mobility shift between MBP-Plk4-T172E-K43M and MBP-Plk4-T172E results from auto-phosphorylation of the latter; and MBP-Plk4-T172E is an active form of Plk4 which was used in subsequent experiments.

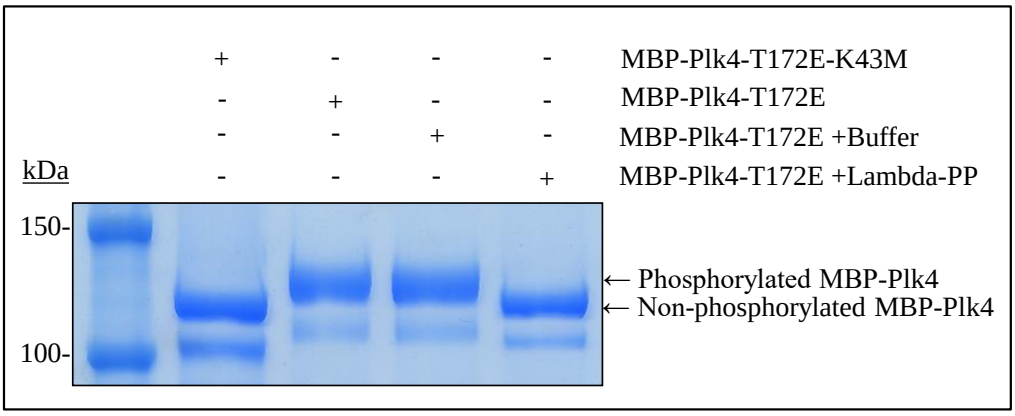

Figure 4-3 MBP-Plk4-T172E auto-phosphorylates but kinase dead MBP-Plk4-T172E-K43M does not. SDS-PAGE showing bandshift due to auto-phosphorylation of MBP-Plk4-T172E compared to the kinase dead MBP-Plk4-T172E-K43M. Bandshift and phosphorylation of MBP-Plk4-T172E is reverted to the level of kinase dead MBP-Plk4-T172E-K43M after treatment with lambda-phosphatase.

Experiments in *C. elegans* have shown that Sas5 (Ana2 homologue) and Sas6 are recruited to the procentriole after Zyg-1 (Plk4 homologue) [53,91]; that the recruitment of Sas6 to the

procentriole is independent of Zyg-1 (Plk4 homologue); and that the kinase is necessary for the maintenance of Sas6 at the centriole which is achieved by Zyg-1 mediated phosphorylation of Sas6 at Ser123 [113]. To study whether Ana2 or Sas6 are substrates of Plk4 phosphorylation in centriole duplication, I applied a similar binding assay as above. I incubated active MBP-Plk4 kinase with several centriolar proteins, which were expressed in *E. coli* and purified onto resin before addition of ^{32}P-γ-ATP in kinase buffer. The proteins tested as potential substrates were MBP-Ana2 and MBP-Sas6; MBP was used as a negative control. After incubation, the resins were washed and subjected to SDS-PAGE; the gel was dried and exposed at -80°C. The autoradiograms showed that MBP-Ana2 but neither MBP nor MBP-Sas6 are Plk4 substrates.

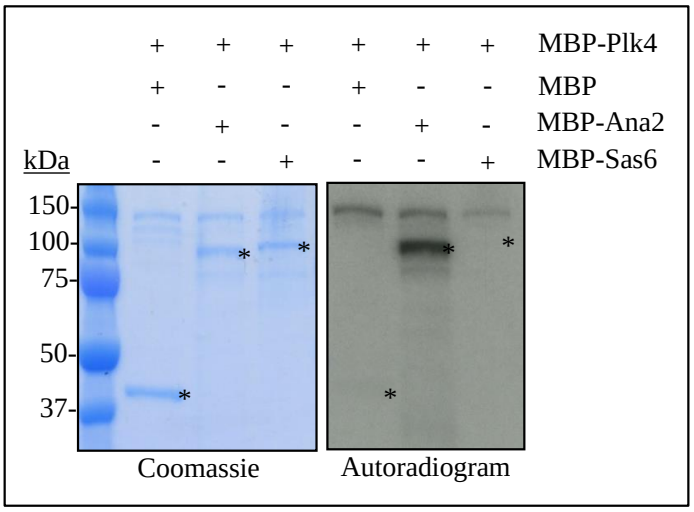

Figure 4-4 Active Plk4 phosphorylates Ana2 but not Sas6. Coomassie stained SDS-PAGE gel and correlating autoradiogram. SDS-PAGE shows MBP, MBP-Ana2 and MBP-Sas6, following incubation with active MBP-Plk4 and ^{32}P-γ-ATP. Autoradiogram shows radioactive signal only for MBP-Ana2, that was phosphorylated directly by active MBP-Plk4. MBP and MBP-Sas6 were not phosphorylated by active Plk4.

After showing that N-terminally MBP-tagged Ana2 is a substrate of Plk4 (Figure 4-4), I tested N-terminally GST-tagged Ana2 protein by *in vitro* phosphorylation assay (Figure 4-5), to confirm that GST-Ana2 can be phosphorylated by active Plk4. For this, I treated GST alone (negative control) or GST-Ana2 on resin, with either MBP-Plk4^{KD} (kinase dead Plk4) or active

MBP-Plk4, under addition of ^{32}P-γ-ATP. This revealed that only GST-Ana2 but not GST-alone was phosphorylated by the active form of Plk4 (Figure 4-5).

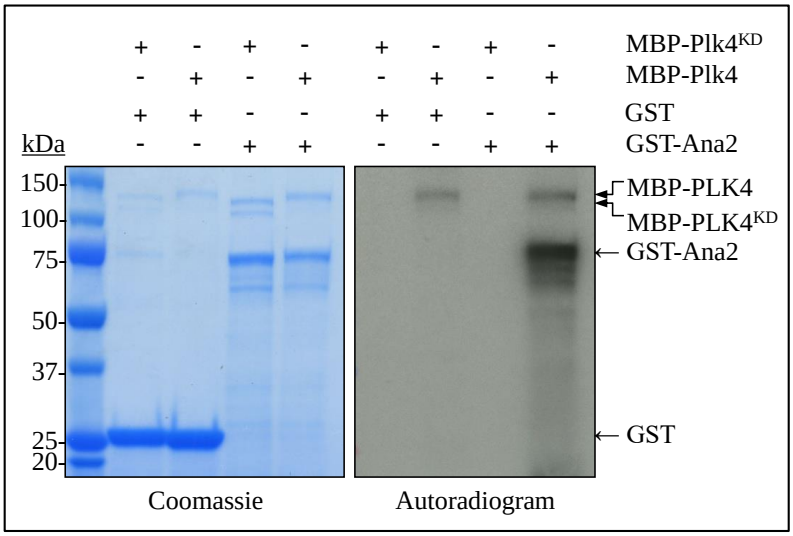

Figure 4-5 Ana2 is phosphorylated by Plk4. GST and GST-Ana2 bound to resin were treated with active MBP-Plk4 or kinase dead MBP-Plk4^{KD} in the presence of ^{32}P-ATP and then subjected to SDS-PAGE and autoradiography. Coomassie stained gel shows protein inputs and bandshift of GST-Ana2, treated with active MBP-Plk4. Bandshift of MBP-Plk4 due to phosphorylation state, as confirmed by ^{32}P signal in the autoradiogram.

4.2.2 Plk4 phosphorylates Ana2 at four main phosphorylation sites which are localised in the conserved Ana2-STAN motif

As shown in section 4.2.1.2, Ana2 is phosphorylated by active Plk4. To identify the Plk4-phosphorylation sites within Ana2, I generated Plk4 phosphorylated Ana2 *in vitro* (GST-Ana2 protein was phosphorylated by active Plk4) and Dr. Dzhindzhev generated Plk4 phosphorylated Ana2 *in vivo* (ProteinA-Ana2 was affinity purified from *Drosophila* cell culture expressing non-degradable Plk4ND), and both samples were analysed by phospho-peptide mapping by mass spectrometry by Dr. Dubski. Table 4‑1 summarises the frequency of particular phospho-peptides detected *in vivo* or *in vitro*. This identified two tryptic peptides

which are highly present in the *in vitro* and *in vivo* samples; namely S318, and the grouped S365, S370 and S373. Significantly, the identified phosphorylated peptides are within the conserved STAN motif of Ana2 (Figure 4-6, Figure 4-7). Other tryptic peptides, which were phosphorylated by Plk4, were also identified by phospho-peptide mapping by mass spectrometry of Ana2 phosphorylated *in vitro* and/or *in vivo* but at a lesser spectral count (Table 4‑1). Several of these were previously reported as phosphorylated in *Drosophila* Kc 167 cells in a phospho-proteome analysis [303].

Figure 4-6 shows the schematic localisation of the identified Plk4 phosphorylation sites within Ana2 in red, the predicted coiled-coil region in green and the conserved STAN motif in blue. The four main Serine residues that are phosphorylated by Plk4 (S318, S365, S370, S373) lie within the conserved Ana2-STAN motif. And all four Serine residues are conserved as Serine/Threonine sites in the STAN motif throughout the analysed species *Homo sapiens*, *Gallus gallus*, *Xenopus laevis*, *Danio rerio*, and *Drosophila melanogaster* (Figure 4-7).

Having determined that full length Ana2 is phosphorylated by Plk4 throughout its sequence, with the C-terminal residues S318, S365, S370 and S373 in the conserved STAN motif being particularly prominent sites, I wished to test the separated N- and C-terminal parts as substrates. I generated two constructs splitting Ana2 to cover aa1-280 and aa281-420. In collaboration with Dr. Dzhindzhev, we then performed an *in vitro* kinase assay using the generated GST-tagged Ana2 fragments bound to resin (GST-Ana2-N, residues 1-280aa and GST-Ana2-C, residues 281-420aa) and treated them with active MBP-Plk4 kinase and ^{32}P-γ-ATP. This indicated that active MBP-Plk4 is able to phosphorylate both GST-Ana2 fragments, GST-Ana2-N and GST-Ana2-C (Figure 4-8). Significantly, the phosphorylation efficiency of GST-Ana2-C is ~2.5 times higher than the GST-Ana2-N fragment.

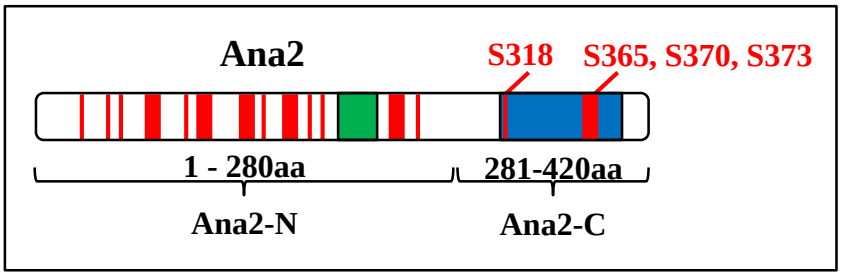

Figure 4-6 Localisation of the Plk4 phosphorylation sites within Ana2 identified by phospho-peptide mapping by mass spectrometry and listed in Table 4-1. Schematic of Ana2 showing the Plk4 phosphorylation sites (red), predicted coiled-coil domain (green) and the conserved STAN motif (blue). The four main Serines phosphorylated by Plk4 *in vitro* and *in vivo* are S318, S365, S370 and S373, which localise within the conserved STAN motif of Ana2.

Table 4-1 Plk4 phosphorylates Ana2 predominantly at residues S318, S365, S370 and S373 within the STAN motif *in vitro* and *in vivo* as identified by phospho-peptide mapping by mass spectrometry. GST-Ana2 was phosphorylated by MBP-Plk4 *in vitro* and *in vivo* ProteinA-Ana2 was affinity purified from *Drosophila* cell culture co-expressing PrA-Ana2 and non-degradable Plk4ND. Each sample was subjected to phospho-peptide mapping by mass spectrometry. The table summarises the number of times a particular phospho-peptide was detected from the *in vitro* and *in vivo* samples. Two tryptic peptides were preferentially phosphorylated, S318 and S365-373 (consisting of S365, S370 and S373).

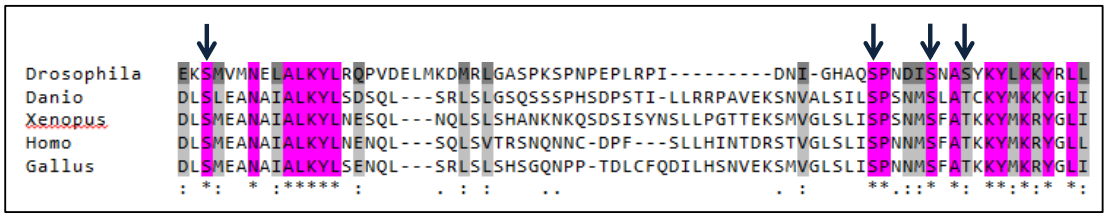

Figure 4-7 Alignment of orthologue Ana2 STAN motif sequences highlighting the four conserved Serines phosphorylated by Plk4. Analysis of Ana2/STIL STAN motif sequences of five species; *Drosophila melanogaster*, *Danio rerio*, *Xenopus laevis*, *Homo sapiens* and *Gallus gallus*. Arrows highlighting the Plk4 phosphorylation sites identified in *Drosophila melanogaster*, S318, S365, S370 and S373. Alignment was generated with Clustal Omega [284].

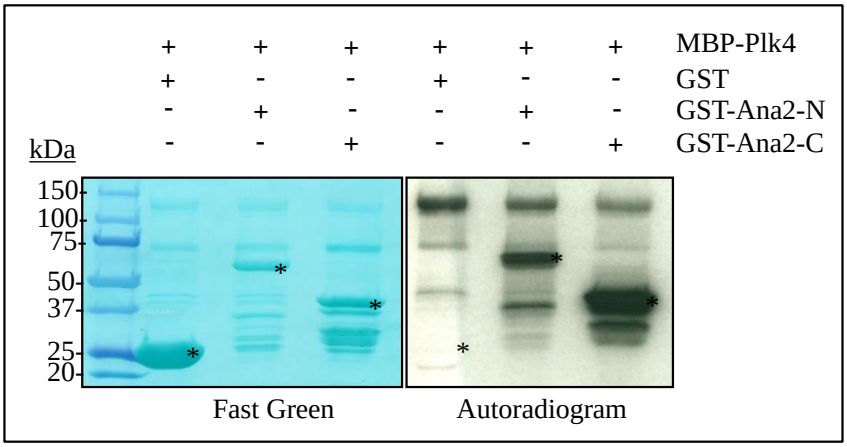

Figure 4-8 MBP-Plk4 phosphorylates Ana2-N (aa1-280) and Ana2-C (aa281-420) *in vitro*. In the presence of ^{32}P-γ-ATP, GST, GST-Ana2-N and GST-Ana2-C were treated with active MBP-Plk4 in a phosphorylation assay, subjected to SDS-PAGE and autoradiography. GST-Ana2-N and GST-Ana2-C show phosphorylation by MBP-Plk4.

4.2.3 Non-phosphorylatable Ana2 leads to loss of centrosomes; phospho-mimicking Ana2 rescues centriole duplication

4.2.3.1 Ana2 is efficiently depleted by dsRNA against Ana2 CDS and Ana2 UTR

Ana2 is a conserved protein, with the most striking region of homology being a predicted coiled-coil region in the central part of the protein and the conserved STAN motif in the C-terminal part (aa315-384). Ana2 and its homologues (Sas5 in *C. elegans*, STIL in *Homo sapiens*) are essential for centriole duplication. I wished to be able to deplete endogenous Ana2 from cultured cells in such a way that I could then express mutant forms of Ana2 in its place. To test the efficiency, I depleted endogenous Ana2 using dsRNA against its UTRs, and asked if I could transfect cells with a rescue construct lacking UTR elements. Depletion of Ana2 with dsRNA against its *CDS* or *UTR* and control RNAi was performed over 12 days with 3 dsRNA treatments every 4 days in collaboration with Dr. Dzhindzhev. Cells were fixed and stained to reveal the centrosome marker D-Plp. I then analysed the cells by automated fluorescent microscopy to determine centrosome numbers after depletion of Ana2 or control-GST (Figure 4-9). Over a time course of 4, 8 and 12 days *GST* RNAi treated cells showed a constant proportion of cells without centrosomes of less than 10%, which is comparable to wild-type *Drosophila* cell culture. Therefore, GST RNAi does not affect centriole duplication. In contrast, depletion of Ana2 using dsRNA against the CDS, led to an increasing percentage of cells without centrosomes; from 27.2% +/- 2.6% on day 4, to 67.7% +/- 4% on day 8, and 94.3% +/- 0.9% on day 12. When Ana2 was depleted via its UTR regions, the percentage of cells without centrosome increased significantly over the analysed time course; from 24% +/- 2.1% on day 4, to 38.5% +/- 3.3% on day 8, and 67.7% +/- 3.5% on day 12. Therefore, depletion of Ana2, either by its CDS or its UTR, results in loss of centrosomes. Ana2 dsRNA directed against the CDS is more effective in preventing centriole duplication than dsRNA against the UTR. Nevertheless, the effect of dsRNA against Ana2's

UTR is substantial (67.7% +/- 3.5% of cells without centrosomes on day 12) compared to the negative GST control (9% +/- 1% of cells without centrosomes on day 12).

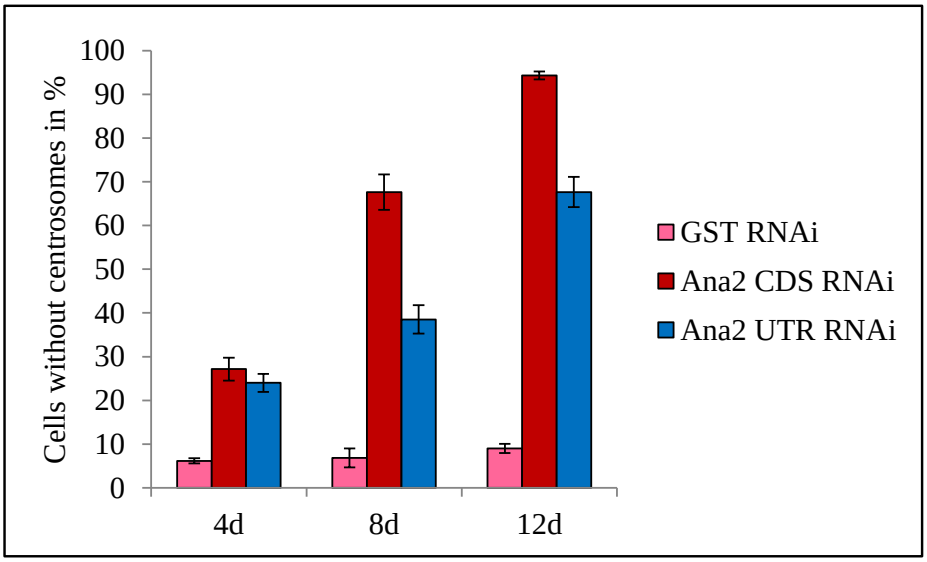

Figure 4-9 Depletion of Ana2 using dsRNA against Ana2 CDS or Ana2 UTRs leads to loss of centrosomes. Cultured *Drosophila* cells were depleted of Ana2 by RNAi with dsRNA against Ana2 CDS or dsRNA against Ana2 UTRs, with GST dsRNA as negative control. Centrosome numbers were scored after each round of RNAi on day 4, day 8 and day 12. Loss of Ana2 causes loss of centrosomes. 3x200 cells; error bars represent standard error.

4.2.3.2 Rescue of Ana2 depletion by Ana2-4D but not Ana2-4A

To test the biological significance of the four Plk4-phosphorylation sites in the STAN motif of Ana2, I performed rescue experiments, to study the effect of Ana2-4A and Ana2-4D on centrosome numbers after depletion of endogenous Ana2 in *Drosophila* cell culture. Ana2-4A and Ana2-4D carry mutations at the four identified Plk4-phosphorylation sites S318, S365, S370, and S373; with S to A (Serine to Alanine) mutations for the non-phosphorylatable Ana2-4A and S to D (Serine to Aspartic acid) mutations for the phospho-mimicking Ana2-4D respectively. In collaboration with Dr. Dzhindzhev, stable cell lines expressing pAct5-Ana2-WT, pAct5-Ana2-4A and pAct5-Ana2-4D, were depleted of endogenous Ana2 by RNAi with dsRNA against Ana2 UTR (versus negative control dsRNA

GST) for 12 days with a depletion round every four days. Cells were fixed and stained to reveal the centrosome markers D-Plp and Asl. DNA was stained with DAPI. Cells were analysed by automated microscopy, to analyse the percentage of cells without centrosomes (Figure 4-10, Figure 4-11). All three cell lines were treated with dsRNA against GST or Ana2 UTR for 12 days respectively, resulting in cells without centrosomes at 4.8% +/- 0.4% versus 11.5% +/- 1% for Ana2-WT expressing cells, 20.8% +/- 0.9% versus 83.5% +/- 0.3% for Ana2-4A expressing cells, and 9.3 % +/- 0.2% versus 22.7% +/- 2.7% for Ana2-4D expressing cells after GST RNAi versus Ana2 UTR RNAi (Figure 4-10). The expression of Ana2-WT and the phospho-mimicking Ana2-4D rescue the depletion of endogenous Ana2 and therefore can fully substitute for the endogenous protein. On the contrary, expression of the transgenic non-phosphorylatable Ana2-4A fails to rescue centrosome numbers, as the percentage of cells without centrosomes is higher after depletion of endogenous Ana2 versus the negative control of GST dsRNA. Additionally, the stable expression of Ana2-4A had a dominant-negative effect on centrosome numbers, with an increase of cells lacking centrosomes in 20.8% +/- 0.9% of cells, compared to 4.8% +/- 0.4% in Ana2-WT expressing cells after control-RNAi (dsRNA GST). Figure 4-11 shows a representative image of cells for each of the three cell lines after depletion of endogenous Ana2 for three rounds over 12 days. In cells expressing Ana2-WT and Ana2-4D, both centrosomal markers D-Plp and Asterless co-localise at the centrosomes whereas the signals for D-Plp and Asterless are greatly lost in the majority of cells expressing Ana2-4A, suggesting loss of centrosomes. Thus, depletion of endogenous Ana2 by its UTR can be rescued by Ana2-WT or Ana2-4D, but not by Ana2-4A. Therefore, the four identified Plk4 phosphorylation sites in the STAN motif of Ana2 (conserved S318, S365, S370, and S373) are functionally necessary to rescue the depletion of endogenous Ana2 and therefore important for centriole duplication.

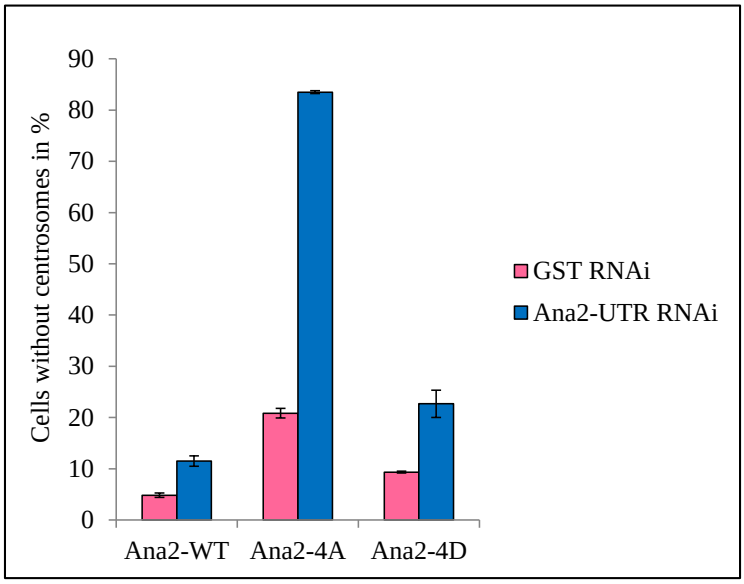

Figure 4-10 Ana2-WT or Ana2-4D but not Ana2-4A rescue the depletion of endogenous Ana2. Endogenous Ana2 was depleted from *Drosophila* cell cultures overexpressing pAct5c-Ana2-WT, pAct5c-Ana2-4A or pAct5c-Ana2-4D for 3 rounds of dsRNA treatment targeting Ana2 UTRs or control GST. Cells with zero centrosomes were counted on day 12. Error bars represent standard error; 3x200 cells counted.

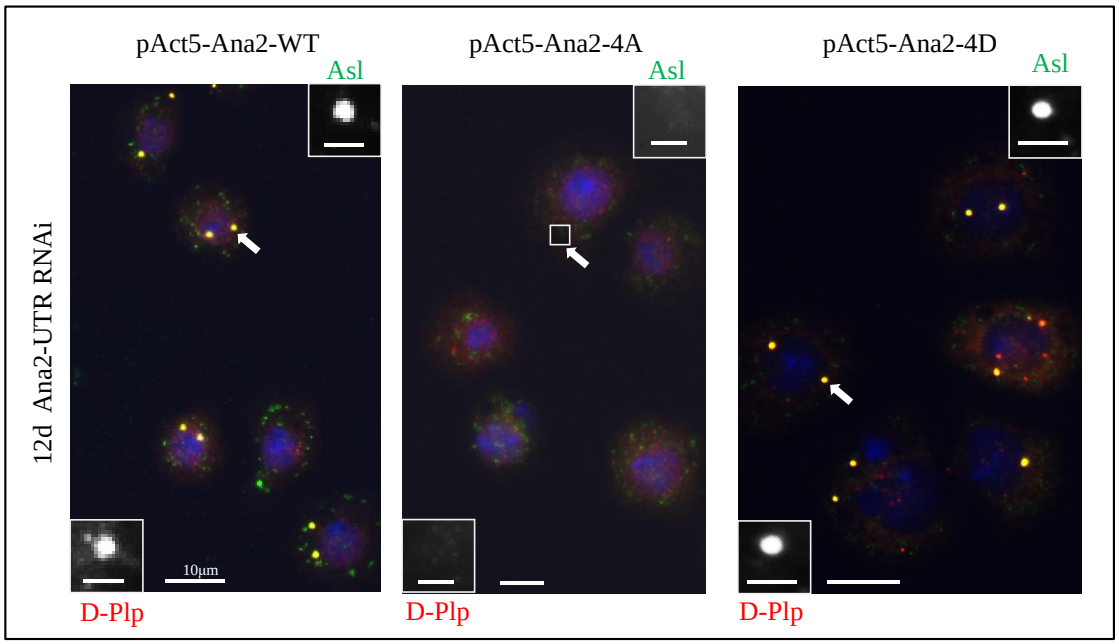

Figure 4-11 Centrosomal markers D-Plp (red) and Asterless (green), after 12 days of Ana2-UTR RNAi in *Drosophila* cell lines overexpressing Ana2-WT, Ana2-4A or Ana2-4D. Insets show enlarged centrosomes from one pole highlighted by arrows in monochrome for D-Plp and Asterless staining; insets scale bar represent 2µm. DNA was stained with DAPI. Main figure scale bars represent 10µm.

4.2.4 Ana2 can interact with Sas6 after it is phosphorylated by Plk4 *in vitro*

Sas5 and Sas6, the *C. elegans* homologues of *Drosophila* Ana2 and Sas6 respectively, are simultaneously recruited to the procentriole in *C. elegans* [53,91]. This raised the question of whether *Drosophila* Ana2 and Sas6 interact with each other. My *in vitro* and *in vivo* studies of direct protein binding (section 4.2.1.1) and mass spectrometry analyses of affinity purified Sas6 or Ana2 from *Drosophila* cell cultures (section 3.2.1.2), did not indicate any interaction between Ana2 and Sas6. However, the finding that Plk4 phosphorylates Ana2 but not Sas6 (section 4.2.2) raised the hypothesis, that in *Drosophila*, Plk4 phosphorylation of Ana2 might be essential for the interaction of Ana2 and Sas6. To analyse this hypothesis, I developed an efficient *in vitro* binding assay to test interactions of Sas6 with pre-phosphorylated Ana2. The final protocol, which was used for the following pre-phosphorylation-binding assays, was established by Dr. Lipinszki (section 2.8.3).

GST-tagged Ana2 and the non-phosphorylatable GST-tagged Ana2-4A were purified from *E. coli* onto resin and treated with active Plk4 (MBP-Plk4) or kinase-dead Plk4 (MBP-Plk4^{KD}) in a phosphorylation assay. Each pre-treated Ana2, Ana2-4A and GST sample (either with active Plk4 or kinase-dead Plk4) was then incubated with ^{35}S-Methionine-labelled Sas6 protein in binding assays, followed by multiple washes of the resin and analysis of the resulting complexes on SDS-PAGE (section 2.8.1). The wash steps remove any free ^{35}S-Methionine-labelled Sas6 from the resin. The SDS-PAGE was then dried and exposed. The resulting autoradiogram shows a signal from ^{35}S-Methionine-labelled Sas6 if it directly bound to a protein on resin (GST, GST-Ana2-WT, GST-Ana2-4A) (left panel of Figure 4-15). Only Plk4-phosphorylated Ana2 binds Sas6 directly *in vitro*, as seen by the detected ^{35}S-Methionine-labelled Sas6 signal in the autoradiogram. Importantly, there is no direct interaction between Ana2 and Sas6, when Ana2 was treated with kinase dead Plk4 (MBP-Plk4^{KD}), confirming the necessity of Plk4-mediated phosphorylation of Ana2, in such that it can interact with Sas6. GST does not interact with Sas6, either when treated with active or kinase dead Plk4. We also found that Ana2-4A, which cannot be phosphorylated by Plk4,

cannot interact with Sas6. This indicates that the phosphorylation of Ana2 by Plk4 is necessary to allow Ana2 to interact with Sas6.

The above findings raised the question of whether Plk4 also regulates this interaction of Ana2 with Sas6 *in vivo*. In collaboration with Dr. Lipinszki, Co-IP studies on extracts of *Drosophila* cells confirmed that Ana2 interacts with Sas6, when it is phosphorylated by Plk4 (Figure 4-12). Transiently transfected *Drosophila* cell cultures co-expressing FLAG-Ana2-WT or FLAG-Ana2-4A with firstly, Sas6-Myc and secondly, non-degradable Plk4 ($Plk4^{ND}$) or kinase dead non-degradable Plk4 ($Plk4^{ND-KD}$) were FLAG immunoprecipitated, followed by SDS-PAGE and Western Blot analyses. Additionally, inputs were subjected to SDS-PAGE and Western Blot analyses. The input samples confirmed the presence of $Plk4^{ND}$ and $Plk4^{ND-KD}$ by anti-Plk4 antibody staining, Ana2 and Ana2-4D by-FLAG antibody staining, Sas6 by anti-Myc antibody staining and as a control anti-α-tubulin. The Western Blot analyses of the FLAG-IPs of the four samples confirm the presence of Ana2 and Ana2-4D in all the samples by anti-FLAG antibody staining. Sas6 was identified only in the FLAG-IP purification co-expressing FLAG-Ana2 with Sas6-Myc and non-degradable $Plk4^{ND}$. Hence, Sas6 is able to interact only with Ana2-WT and when Ana2 is phosphorylated by Plk4 *in vivo*. This confirms our previous *in vitro* observations.

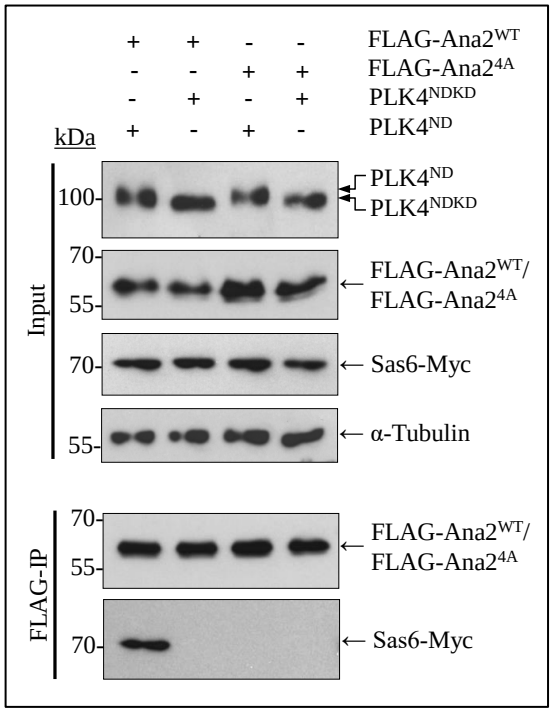

Figure 4-12 Plk4 phosphorylation of Ana2 triggers direct interaction of Ana2 and Sas6 *in vivo*. *Drosophila* cell cultures transiently overexpressing FLAG-Ana2-WT or the four Serine substitution mutant FLAG-Ana2-4A with Sas6-Myc and either the non-degradable degron mutant Plk4ND or the non-degradable kinase dead degron Plk4^{ND-KD} were subjected to FLAG-immunoprecipitation. Inputs of the *Drosophila* cell cultures and the FLAG-immunorecipitations were analysed by SDS-PAGE and Western blotting to reveal the indicated antigens. Experiment and image by Dr. Lipinszki [296].

4.2.4.1 The C-terminus of Ana 2 is nessessary for interaction with Sas6 *in vitro*

In section 4.2.4, I show that Sas6 directly binds Ana2 that was phosphorylated by Plk4, with the four main phosphorylation sites located within the Ana2-C-terminus (Figure 4-6). I wished to explore the possibilities if firstly, Sas6 binds only the Plk4-phosphorylated Ana2-C-terminus, or if secondly, Sas6 binds the Ana2-N-terminus, made accessable due to a confirmation change in Ana2 upon its phosphorylation by Plk4. To answer this question, I tested if Sas6 can directly bind Ana2-N-terminus (aa1-280) or Ana2-C-terminus (aa281-420), after treatment with active or kinase dead Plk4 (Figure 4-13). Together both Ana2 fragments

cover the full length of the Ana2 sequence, with GST-Ana2-C containing only the four identified Plk4-phosphorylated Serine residues of the conserved STAN motif (S318, S365, S370, S373). The phosphorylation-binding-assays (section 2.8.3) confirm that after treatment with active Plk4, the Ana2-C-terminus but not Ana2-N-terminus interacts directly with Sas6. Treatment with kinase-dead Plk4 does not lead to their interaction. Plk4-phosphorylated Ana2-WT and Ana2-C-terminus bind Sas6 equally efficient, determined by equal Sas6 signals on the autoradiogram. In collaboration with Dr. Dzhindzhev, the phosphorylation assay of GST-Ana2-C-WT and GST-Ana2-C-4A treated with active MBP-Plk4 and ^{32}P-γ-ATP confirms that Ana2-C-terminus is phosphorylated by active Plk4 (Figure 4-14). Thus, the Plk4-phosphorylated Ana2-C-terminus is efficient and sufficient for direct interaction with Sas6.

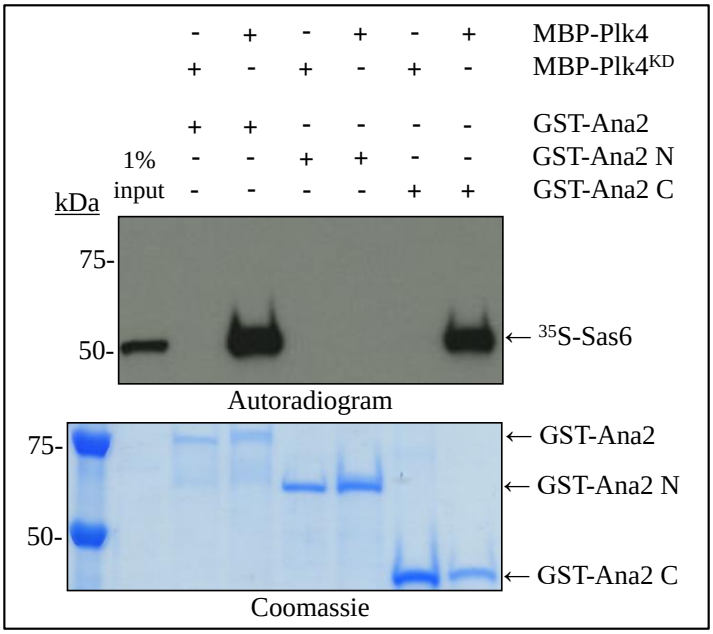

Figure 4-13 Plk4-phosphorylated Ana2-C (aa281-420) interacts directly with Sas6. GST-Ana2, GST-Ana2-N and GST-Ana2-C were treated with active or kinase dead Plk4 (MBP-Plk4 and MBP-Plk4^{KD} respectively) and incubated with ^{35}S-Methionine-labelled Sas6. The complexes were subjected to SDS-PAGE and autoradiography. SDS-PAGE shows comparable protein levels loaded of each protein sample. The respective autoradiogram shows 1% input of ^{35}S-Methionine-labelled Sas6 and interaction of GST-Ana2 and GST-Ana2-C with ^{35}S-Methionine-labelled Sas6 in a Plk4-phosphorylation dependent manner. GST-Ana2-N does not interact with ^{35}S-Methionine-labelled Sas6, independent of treatment with Plk4.

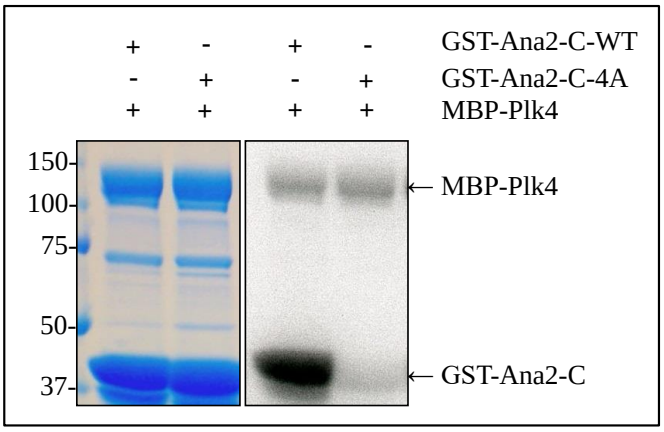

Figure 4-14 Plk4 phosphorylates GST-Ana2-C (aa281-420) at the four conserved Serines of Ana2-STAN motif. GST-Ana2-C (aa281-420) and GST-Ana2-C-4A (S318A, S365A, S370A, S373A) were incubated with active MBP-Plk4 and ^{32}P-γ-ATP, then subjected to SDS-PAGE and autoradiography. GST-Ana2-C is phosphorylated by MBP-Plk4. The Serine to Alanine substitution mutant (GST-Ana2-C-4A) is not phosphorylated by Plk4. The four conserved Serine residues in Ana2-STAN in the Ana2-C are necessary for phosphorylation by Plk4.

4.2.5 Plk4 phosphorylation of the four conserved Serines S318, S365, S370 and S373 within the Ana2-STAN motif are necessary for its interaction with Sas6

In section 4.2.4, I showed that Sas6 interacts with Ana2, when Ana2 is phosphorylated by Plk4. On the other hand, Ana2-4A, which has its four main Plk4 phosphorylation Serine residues S318, S365, S370 and S373 mutated to Alanine, cannot be phosphorylated. This raises the question of which of the four Serine residues contributes mainly to the Plk4-mediated phosphorylation of Ana2, that permits this interaction. To address this, I generated, expressed and purified Ana2 with S(erine) to A(lanine) mutations for each individual Serine residue identified as Plk4 phosphorylation residues in the conserved Ana2 STAN motif (section 4.2.4.1), generating GST-Ana2-S318A, GST-Ana2-S365A, GST-Ana2-S370A, and GST-Ana2-S373A. These fusion proteins were bound to resin and subjected to active Plk4 (MBP-Plk4) or kinase dead Plk4 (MBP-Plk4^{KD}) before incubation with ^{35}S-Methionine-labelled Sas6 (section 2.8.3). The samples were then washed and analysed on SDS-PAGE,

followed by autoradiography of the dried gels (Figure 4-15). The autoradiogram shows reduced ^{35}S-Methionine-Sas6 binding with each of the Ana2 single-site mutation proteins, when treated with active Plk4, compared to the interaction with Plk4-phosphorylated Ana2-WT protein. The strongest reduction of the binding of ^{35}S-Methionine-labelled Sas6 to Ana2 can be seen when S373 or S370 are mutated to Alanine, with the latter showing the greatest effect. Control binding assays using kinase dead Plk4 show weak background binding of ^{35}S-Methionine-labelled Sas6 to the Ana2 single-site mutation proteins evident in long exposures.

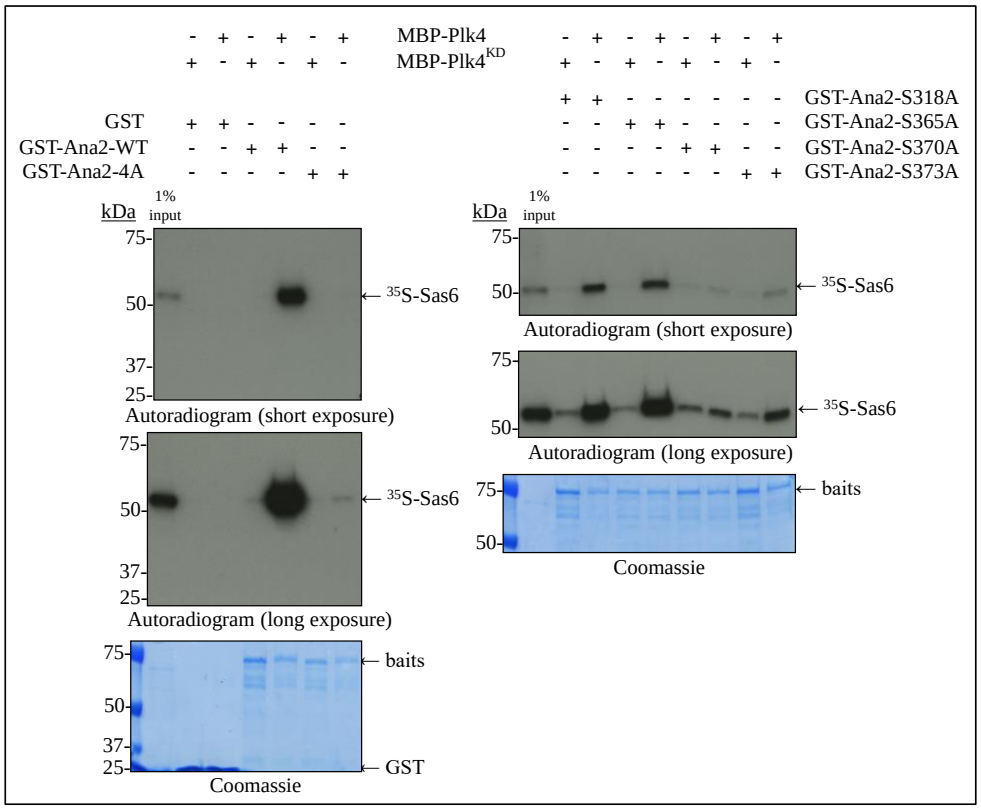

Figure 4-15 Plk-4 mediated phosphorylation of four conserved Serines within the Ana2-STAN motif is essential for its interaction with Sas6. Alanine substitution mutation of all four conserved Serines within the Ana2-STAN motif is necessary to abolish the Plk4-mediated interaction of Ana2 with Sas6. Individual Serine to Alanine substitutions do not fully abolish the interaction. S370A results in the greatest reduction of Sas6 binding to Ana2. GST, GST-Ana2-4A and individual Serine to Alanine mutation GST-Ana2 proteins (GST-Ana2-S318A, GST-Ana2-S365A, GST-Ana2-S370A, GST-Ana2-S373A) were treated with active or kinase dead Plk4 MBP-Plk4 and MBP-Plk4^{KD} respectively, followed by incubation with ^{35}S-Methionine-labelled Sas6. Complexes were subjected to SDS-PAGE and autoradiography.

In summary, mutations of individual Serine residues in the conserved STAN motif of Ana2 do not abolish the interaction of Sas6 with phosphorylated Ana2 although mutation of S370 has a significant effect. Together our findings point to the importance of phosphorylation of the four conserved Serine residues in the Ana2-STAN motif for interaction with Sas6 and thus the centriole duplication pathway.

4.2.5.1 Plk4-phosphorylation of all four conserved Serine residues in the STAN motif contribute to the direct interaction of Ana2-C and Sas6

The data provided in section 4.2.5 shows that Plk4-phosphorylation of all four conserved Serine residues in the Ana2-STAN motif, rather than a single site, are necessary for efficient direct interaction with Sas6. In section 4.2.4 and 4.2.4.1 I show that full-length Ana2 and Ana2-C-terminus, both Plk4-phosphorylated, bind Sas6 with equal efficiency. Therefore, I wanted to test if single mutations of the four conserved Serine residues in Ana2-C-terminus behave like their single mutations in full-length Ana2 or if the absence of Ana2-N-terminus might affect interaction with Sas6. I introduced single (S)erine to non-phosphorylatable A(lanine) mutations at S318A, S365A, S370A and S373A in Ana2-C-terminus. Each mutation lowers the efficiency of Ana2-C to bind Sas6 but no single mutation abolishes the interaction with Sas6 completely (Figure 4-16, right panel). The mutation of S373A and particularly S370A reduce the level of Sas6 binding to Plk4-phosphorylated Ana2-C the greatest. The interaction between Ana2-C-terminus and Sas6 can still be seen when only the three most C-terminal of the four Serine residues are mutated to non-phosphorylatable A(lanine) in Ana2-C-3A (S365A, S370A, and S373A). Thus, the findings for Ana2-C are in line with the findings for full-length Ana2 that all four conserved phosphorylation sites in Ana2-STAN contribute to the interaction of Ana2-C/Ana2 with Sas6, but S370 contributes the greatest.

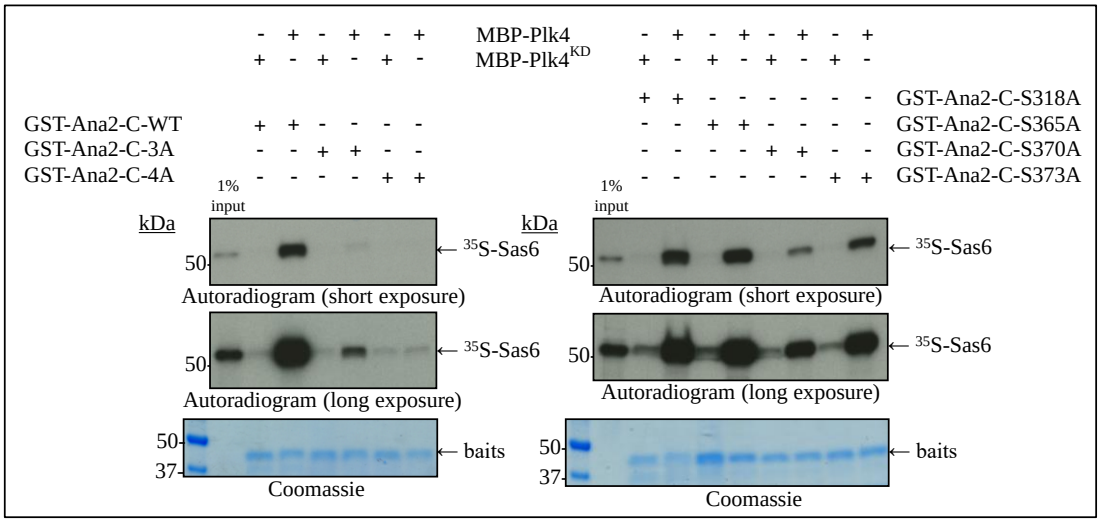

Figure 4-16 Plk-4 mediated phosphorylation of all four conserved Serines within the Ana2-STAN motif is essential for the interaction of GST-Ana2-C-terminus (aa281-420) with Sas6. GST-Ana2-C, GST-Ana2-C-3A, GST-Ana2-C-4A and individual Serine to Alanine mutation GST-Ana2-C proteins (GST-Ana2-C-S318A, GST-Ana2-C-S365A, GST-Ana2-C-S370A, GST-Ana2-C-S373A) were treated with active or kinase dead Plk4 (MBP-Plk4 and MBP-Plk4^{KD} respectively), followed by binding assay with ^{35}S-Methionine-labelled Sas6. Complexes were subjected to SDS-PAGE and autoradiography. Coomassie stainings show protein inputs of GST-Ana2-C constructs on residue. Autoradiogram (left) show abolished interaction between Sas6 and Ana2-C-4A only. Ana2-C-3A alone (S365A, S370A, S373A, left) and individual Ana2-C mutants (right) cannot fully inhibit interaction with Sas6. Importantly, S370A resulting in the greatest reduction of Sas6 binding to Ana2-C. The Alanine substitution mutation of all four conserved Serines within the Ana2-STAN motif is necessary to abolish the Plk4-mediated interaction of Ana2-C with Sas6.

4.2.6 Ana2-4A does not bind Sas6 but Ana2-4D does

As shown in section 4.2.3.2, Ana2-4A causes loss of centrosomes in the absense of wild-type Ana2 and expression of Ana2-4D and Ana2-WT rescues the loss of centrosomes. Ana2, phosphorylated by Plk4, interacts with Sas6 *in vitro* and *in vivo* (section 4.2.4). Non-phosphorylatable Ana2-4A does not interact with Sas6 *in vitro* and phosphorylation of all four Serine residues (S318, S365, S370, S373) is necessary for interaction of Ana2 with Sas6 (section 4.2.4 and 4.2.5). Together, this raises the hypothesis that the observed loss of centrosomes in Ana2-4A expressing cells (section 4.2.3.2) results from lack of interaction of

Ana2 with Sas6, due to the non-phosphorylation of the Ana2-STAN motif by Plk4. Therefore, I analysed if the phosphomimick Ana2-4D can interact with Sas6 *in vitro* or if the interaction of Ana2 and Sas6 is otherwise dependent on Plk4 and not alone dependent on the Ana2-STAN motif phosphorylation by Plk4. To this end, I used GST-alone, GST-Ana2, GST-Ana2-4A and GST-Ana2-4D that I treated with active MBP-Plk4 or kinase dead MBP-Plk4^{KD} and then subjected to a binding assay with ^{35}S-Methionine-labelled Sas6 (section 2.8.3). This showed that GST-Ana2 interacts strongly with Sas6 only after treatment with active Plk4 but shows weak background binding for the GST-Ana2 treated with kinase dead Plk4. GST-Ana2-4A does not interact with Sas6 (independent of treatment with active or kinase dead Plk) (Figure 4-17). On the other hand, GST-Ana2-4D which phosphomimicks the phosphorylation of the Ana2-STAN motif by Plk4, shows a strong interaction with ^{35}S-Methionine-labelled Sas6 independent of treatment with active or kinase dead Plk4. Thus the four conserved Serines in the Ana2-STAN motif must be phosphorylated by Plk4 to allow for the specific interaction of Sas6 with Ana2.

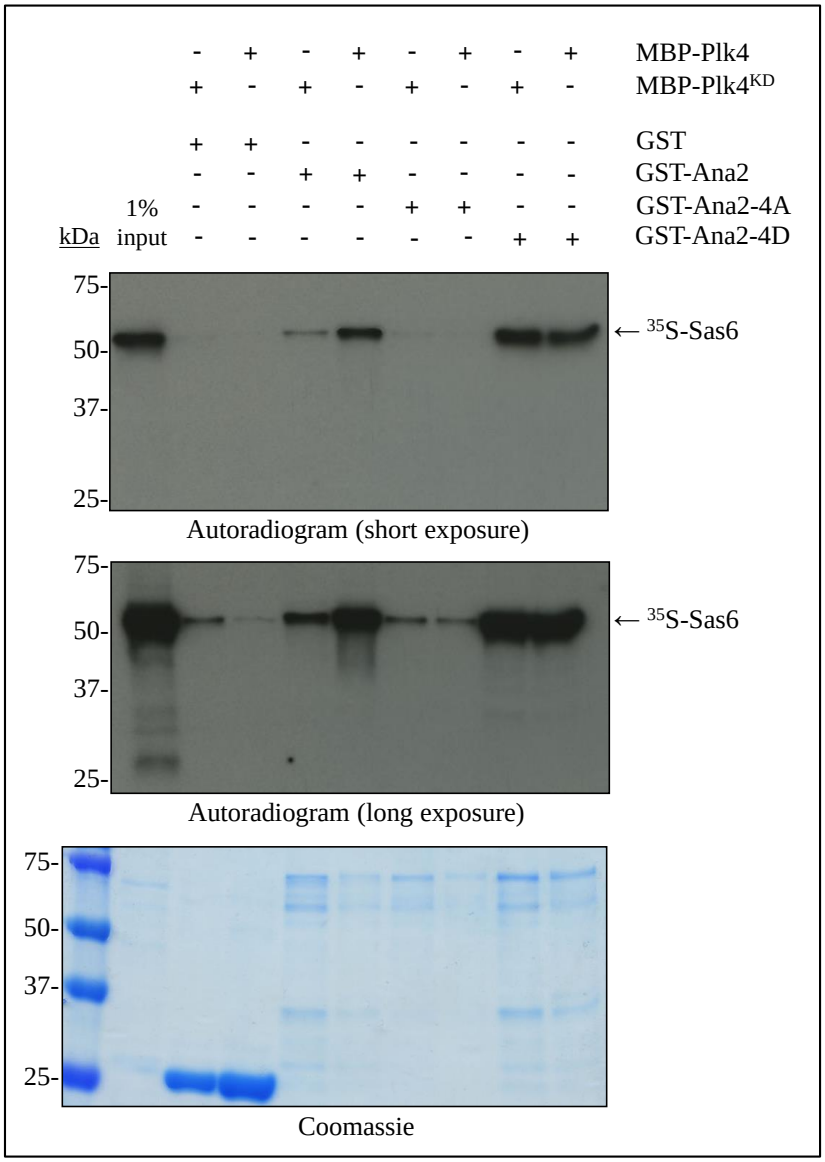

Figure 4-17 Ana2-4D interacts with Sas6 independently of Plk4 treatment *in vitro*. GST, GST-Ana2, GST-Ana2-4A and GST-Ana2-4D were treated with active or kinase dead Plk4 (MBP-Plk4 and MBP-Plk4^{KD} respectively) and incubated with ^{35}S-Methionine-labelled Sas6. The complexes were subjected to SDS-PAGE and autoradiography. Interaction of Sas6 with Ana2 is dependent on phosphorylation of the four conserved Serines within the Ana2-STAN motif, with Serine to Alanine mutations (non-phosphorylatable mutant) abolishing interaction, and Serine to Aspartic acid mutations (phospho-mimicking mutant) exhibiting interaction independent of pre-Plk4-treatment of Ana2.

4.2.7 Selective regulation of Ana2 binding by Plk4 phosphorylation

The interaction of Sas6 and Ana2 early on in the assembly of the new daughter centriole during centriole duplication is conserved. In *C. elegans* Spd2 recruits Zyg-1 and then Sas5 and Sas6 assemble to the forming procentriole [53,91]. However other screens have identified further proteins involved in the assembly of the daughter centriole, suggesting that other protein interactions might be regulated by Plk4 mediated phosphorylation.

This led me to test whether further centriole duplication proteins interact with Ana2 downstream of its phosphorylation by Plk4. I tested whether Ana1, Bld10, Rcd4 and Sas4 proteins, that are known to be involved in centriole duplication [131,288], might preferentially interact with Plk4-phosphorylated Ana2 (Figure 4-18). I treated GST-Ana2-WT with active or kinase dead Plk4, followed by incubation with ^{35}S-Methionine-labelled protein Ana1, Bld10, Rcd4, Sas4 and Sas6. The complexes were then analysed by SDS-PAGE and autoradiography (Figure 4-18). I found that Ana2 interacts with Sas4 independent of whether treated with active or kinase dead Plk4. Similarly, interaction of Bld10 occurred with phosphorylated and non-phosphorylated Ana2 but the interaction increases significantly when Ana2 is phosphorylated by Plk4. Rcd4 and Ana1 do not show any interaction with phosphorylated or non-phosphorylated Ana2. And as previously shown, Plk4-phosphorylated Ana2 interacts with Sas6 (section 4.2.4). These results show and strengthen the finding of the importance and specificity of the phosphorylation of Ana2 to fully trigger its interaction with Sas6.

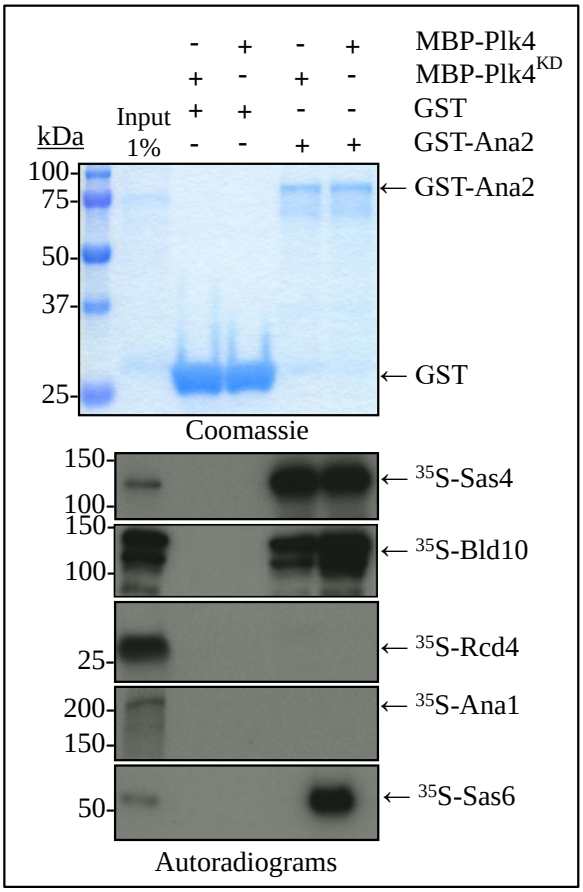

Figure 4-18 Interactions of different centriolar proteins with Ana2 following Plk4-phosphorylation of Ana2. GST-Ana2 was treated with active or kinase dead Plk4 (MBP-Plk4 and MBP-Plk4^{KD} respectively) and incubated with ^{35}S-Methionine-labelled Sas4, Bld10, Rcd4, Ana1 or Sas6. The complexes were subjected to SDS-PAGE and autoradiography. SDS-PAGE shows representative protein inputs of GST and GST-Ana2. Sas6 interacts with pre-phosphorylated Ana2 (MBP-Plk4 treated) but does not interact with Ana2 when treated with kinase dead Plk4 (MBP-Plk4^{KD}). Sas4 interacts with Ana2 independently of its phosphorylation state. Bld10 shows interaction with Ana2 but Plk4-mdiated phosphorylation of Ana2 increases the interaction. Rcd4 and Ana1 do not show interaction with Ana2, independent of treatment with active or kinase dead Plk4.

4.2.8 Physical interaction of Ana2 and Sas6

4.2.8.1 Plk4-mediated phosphorylation of the conserved Ana2-STAN motif is sufficient for binding of Sas6 to Ana2 *in vitro*

After I determined that the C-terminal Ana2-fragment (aa281-420), which contains the STAN motif and is phosphorylated by Plk4, is sufficient to bind Sas6, I wished to determine the smallest Ana2 region necessary for interaction with Sas6. As we know the signifiance of the STAN motif for Plk4-phosphorylation and as the STAN motif is conserved between species, I focused on this C-terminal Ana2 region. Therefore I generated Ana2-fragments which contain the STAN motif only (aa315-384), and constructs with additional sequence upstream and/or dowstream of the STAN motif (Figure 4-19). The Ana2-STAN constructs I made were: Ana2 aa315-384 (STAN only), Ana2 aa305-394, Ana2 aa295-404 and Ana2 aa315-420 (Figure 4-19), and Ana2 full length and Ana2-C (aa281-420) as controls. I expressed and purified the Ana2-STAN protein samples onto resin (section 2.5.1) and performed Plk4 phosphorylation assays, using active or kinase dead Plk4, followed by binding assays with ^{35}S-Methionine-labelled Sas6 (section 2.8.3). Figure 4-20 shows the coomassie stainings and autoradiograms of the binding assays of ^{35}S-Methionine-labelled Sas6 with the analysed Ana2 fragments, Ana2-FL and Ana2-C as controls. Significantly, when the Ana2 constructs are treated with kinase dead Plk4, none of them interact with ^{35}S-Methionine-labelled Sas6. On the other hand, when these Ana2 constructs are treated with active Plk4 kinase, all interacted with ^{35}S-Methionine-labelled Sas6 but with different efficiencies. Similar binding of ^{35}S-Methionine-labelled Sas6, as observed with Ana2-WT and Ana2-C can be seen for Ana2-STAN (aa315-384) and Ana2-aa315-420. The further two Ana2-STAN constructs analysed (aa295-404 and aa305-394) did not interact as strongly with ^{35}S-Methionine-labelled Sas6. In summary, the Ana2-STAN motif alone interacts as efficiently as Ana2-C with ^{35}S-Methionine-labelled Sas6 when phosphorylated by Plk4.

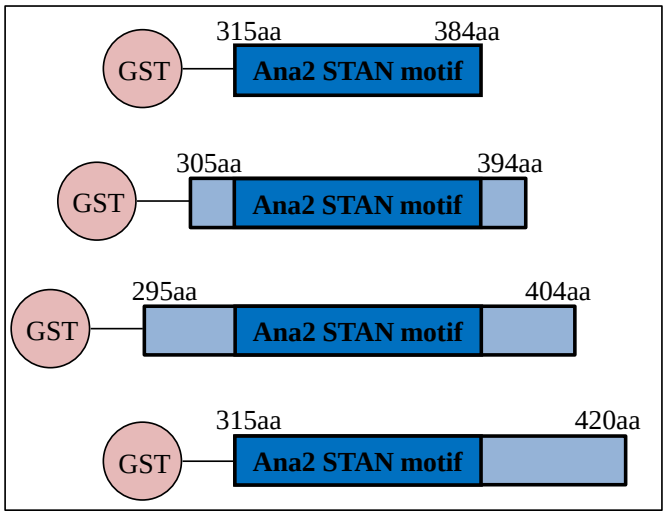

Figure 4-19 Schematic summary of Ana2-STAN constructs analysed for interaction with Sas6. Four N-terminal GST-tagged Ana2 constructs were generated: the first containing the Ana2-STAN motif only (aa315-384); the second including 10 additional amino acids upstream and downstream of the Ana2-STAN motif (aa305-394); the third including 20 additional amino acids upstream and downstream of the Ana2-SAN motif (aa295-404); and the fourth including the C-terminal part of Ana2 sequence after the STAN motif (aa315-420).

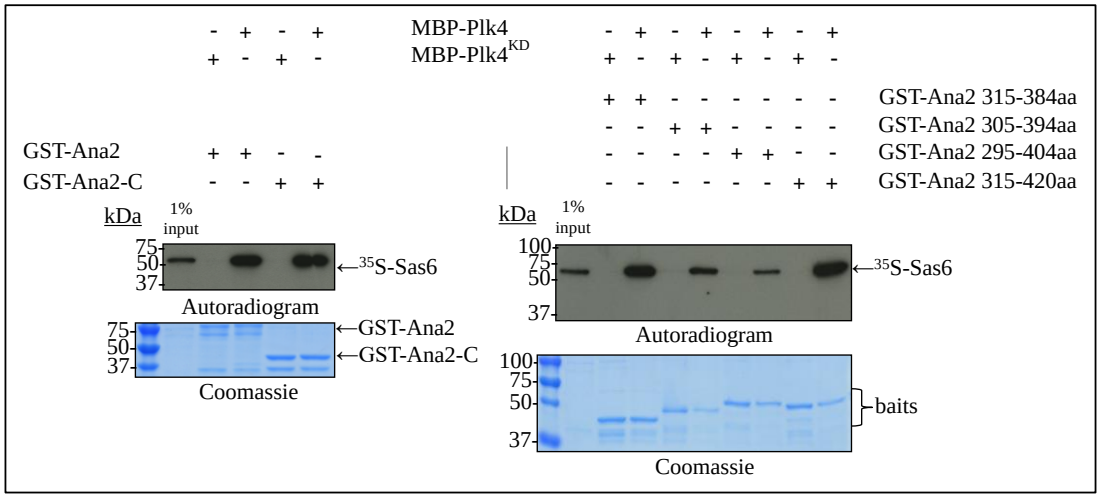

Figure 4-20 Plk4-phosphorylated Ana2-STAN motif is sufficient to interact with Sas6. GST-Ana2, GST-Ana2-C and the four GST-Ana2 constructs summarised in Figure 4-19 were treated with active or kinase dead Plk4 (MBP-Plk4 and MBP-Plk4^{KD} respectively) and incubated with ^{35}S-Methionine-labelled Sas6. Complexes were subjected to SDS-PAGE and autoradiography. Coomassie stainings show bait protein amounts. Autoradiograms show interaction of ^{35}S-Methionine-labelled Sas6 with all phosphorylated Ana2 constructs. GST-Ana2-STAN-only (aa315-384) being the smallest construct interacting as efficiently as GST-Ana2 full-length with Sas6.

4.2.8.2 The aa276-432 coiled-coil segment of Sas6 interacts with Ana2 that has been phosphorylated by Plk4

From section 4.2.8.1, we know that the C-terminal STAN motif of Ana2 is the smallest Ana2 domain which, after it has been phosphorylated by Plk4, interacts with Sas6. But what is the reciprocal domain within Sas6 that interacts with Ana2? To answer this question I generated Sas6 constructs representing the N-terminal head domain of Sas6 (aa1-180), the majority of the predicted coiled-coil domain of Sas6 (aa181-408), a construct combining these two regions (aa1-408), and a construct representing the whole coiled-coil domain with its most C-terminal unstructured region (aa181-472). The generation of the unstructured C-terminus alone or with additional amino acids from the most C-terminal part of the coiled-coil domain (aa421-472) was not possible, due to the small fragment size of 64aa and the size limitations of the *in vitro* transcription-translation system.

In collaboration with Dr. Lipinszki, these constructs were subjected to binding assays with ^{35}S-Methionine-labelled Ana2 that showed only one constructs was able to interact with Ana2, namely Sas6 aa181-472, which represents the whole coiled-coil and C-terminal unstructured domain of Sas6. Thus, the Sas6 N-terminal head domain alone and the Sas6 head domain together with the majority of the coiled-coil domain (aa1-180 and aa1-408 respectively) do not interact with Ana2. This raises the question of which specific region of Sas6 is necessary for interaction with Ana2. From the initial interaction assays it appeared possible that the regions of Sas6 which may interact with Ana2 are: the whole coiled-coil region, a C-terminal part of the coiled-coil region, the unstructured Sas6-C-terminus, or indeed the unstructured Sas6-C-terminus together with the whole coiled-coil region or together with a C-terminal fragment of the coiled-coil region. To distinguish these possibilities, I generated constructs of Sas6 protein fragments for *in vitro* transcription-translation, which were truncated N-terminal of the identified Sas6 fragment that interacts with phosphorylated Ana2 (Sas6 aa181-472) or C-terminal of full-length Sas6. Figure 4-21 summarises the constructs I generated and their ability to interact with Plk4-phosphorylated Ana2; dark blue represents a strong interaction, light blue a good interaction and yellow no interaction. I generated ^{35}S-Methionine-labelled Sas6 protein fragments by *in vitro*

transcription-translation reactions and carried out binding assays with GST-Ana2 (pre-treated with active or kinase dead Plk4). I then subjected the complexes to SDS-PAGE and exposed dried gels to autoradiography. The constructs with N-terminal truncations were Sas6: aa221-472, aa261-472, aa266-472, aa271-472, aa276-472, aa291-472, aa295-472, aa341-472, aa351-472, aa361-472, aa371-472 and aa381-472. The smallest Sas6 construct that shows good interaction with phosphorylated Ana2 is Sas6 aa276-472 (Figure 4-22). The additional constructs analysed were truncated from the C-terminus of full-length Sas6: aa1-462, aa1-452, aa1-442, aa1-437, aa1-432, aa1-427, aa1-422, aa1-414, and aa1-412. The most truncated Sas6 fragment still showing good interaction with phosphorylated Ana2 was Sas6 aa1-432 (Figure 4-23). In summary, these findings show that Sas6 aa1-432 and Sas6 aa276-472 are the most C- and N-terminal truncated Sas6 fragments respectively, that interact with phosphorylated Ana2 (Figure 4-22, Figure 4-23). This experiment defines the Sas6 domain directly interacting with phosphorylated Ana2 *in vitro* as aa276-432 (Figure 4-21, Figure 4-24). From structural Sas6 protein predictions, this suggests, that it is the C-terminal part of the coiled-coil domain of Sas6 that interacts with Plk4-phosphorylated Ana2.

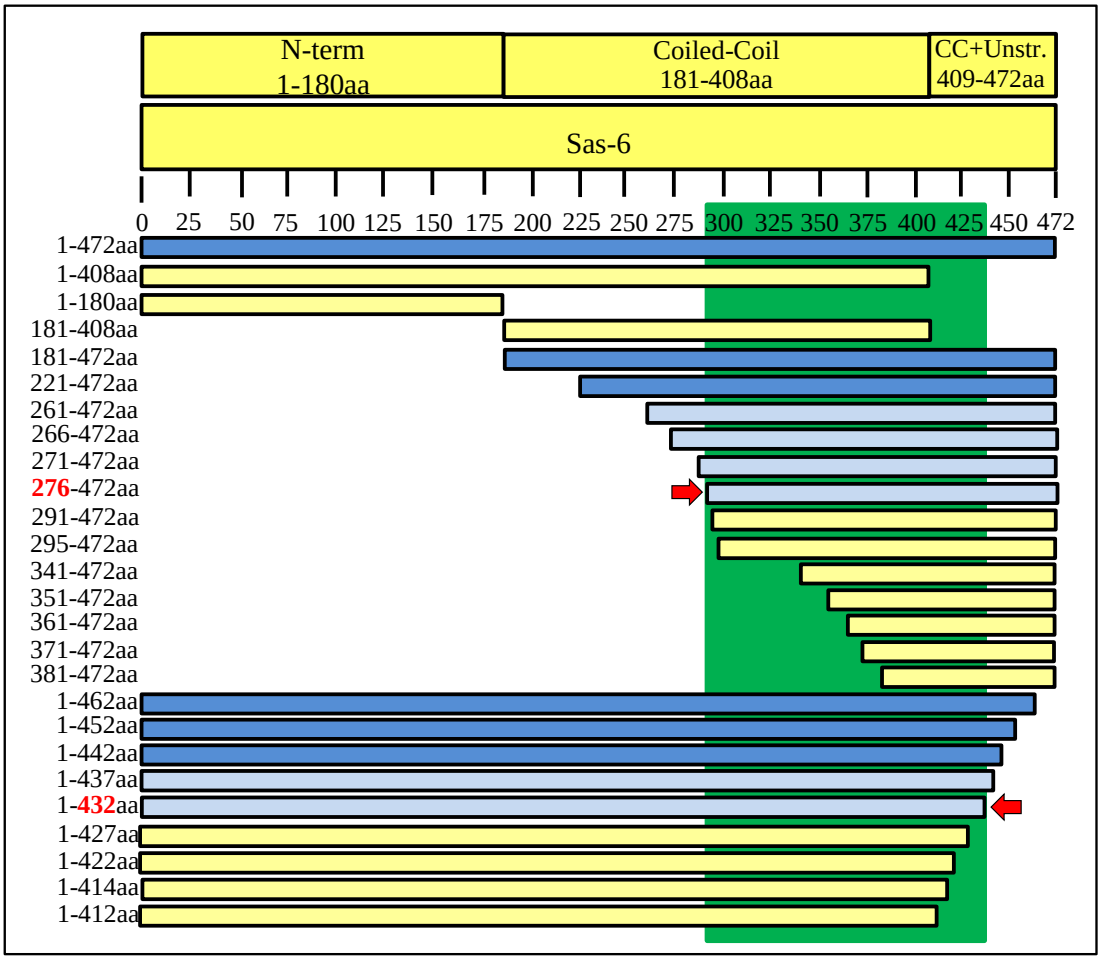

Figure 4-21 Schematic overview of Sas6 constructs, which were studied in an *in vitro* screen for interaction with Plk4-phosphorylated Ana2, determines Sas6 aa276-432 as the most N- and C-terminal truncated region interacting with Ana2. GST-Ana2 was treated with active or kinase dead Plk4 (MBP-Plk4 or MP-Plk4^{KD} respectively) and incubated with *in vitro* transcribed and translated ^{35}S-Methionine-labelled Sas6 constructs summarised. Complexes were subjected to SDS-PAGE and autoradiography. Green background highlights the smallest Sas6 region directly interacting with Plk4-phosphorylated Ana2 *in vitro*. Sas6 constructs and their individual interaction with Plk4-phosphorylated Ana2 are visualised in yellow (no interaction), light blue (good interaction) and darker blue strong interaction). Red arrows indicating the most N- and C-terminal truncated Sas6 constructs still interacting efficiently with Plk4-phosphorylated Ana2.

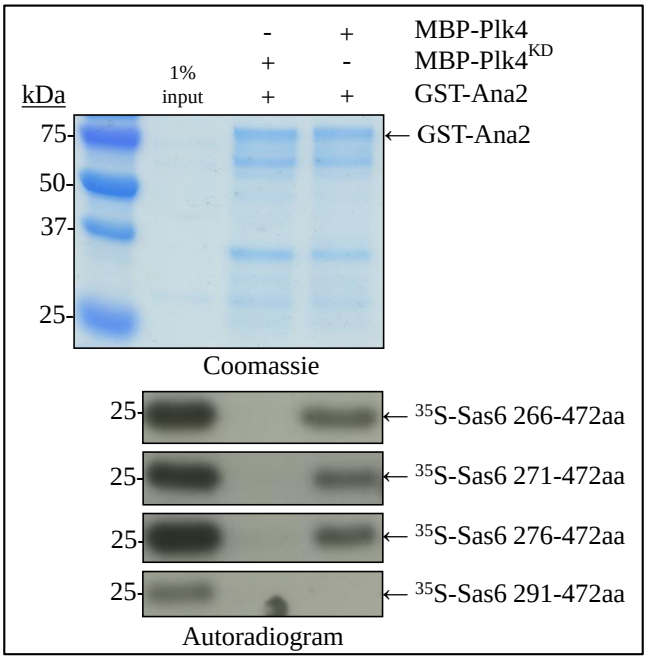

Figure 4-22 Most N-terminal truncated Sas6 construct interacting with Plk4-phosphorylated Ana2 defined as Sas6 aa276-472. GST-Ana2 was treated in a phosphorylation assay with active MBP-Plk4 or kinase dead MBP-Plk4^{KD} and incubated with different ^{35}S-Methionine-labelled Sas6 constructs truncated from the N-terminus in direct binding assays *in vitro*. Complexes were subjected to SDS-PAGE and autoradiography. The Coomassie stained gel shows GST-Ana2 inputs. The autoradiograms show four of the analysed Sas6 constructs, including the smallest (Sas6 aa276-472) and two larger Sas6 fragments (Sas6 aa271-472 and aa266-472) that interact with Plk4-phosphorylated Ana2, and a smaller Sas6 construct (Sas6 aa291-472) that does not interact with Ana2. Summary of all analysed Sas6 constructs in Figure 4-21.

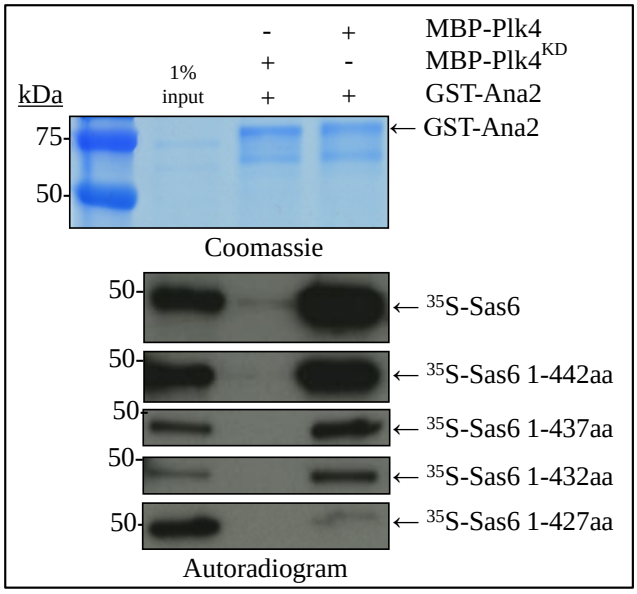

Figure 4-23 Sas6 construct most truncated from the C-terminus and still interacting with Plk4-phosphorylated Ana2 is Sas6 aa1-432. GST-Ana2 was treated with active MBP-Plk4 or kinase dead MBP-Plk4^{KD} in a phosphorylation assay, and incubated with different ^{35}S-Methionine-labelled Sas6 constructs truncated from the C-terminus in *in vitro* binding assays. Complexes were subjected to SDS-PAGE and autoradiography. Coomassie shows GST-Ana2 protein inputs. Autoradiograms show four of the analysed Sas6 constructs in comparison to full-length Sas6 interacting with Plk4-phosphorylated Ana2. Sas6 aa1-427 lacking interaction with Ana2, and Sas6 aa1-432 and larger fragments (aa1-437, aa1-442) interacting with Plk4-phosphorylated Ana2. Summary of all analysed Sas6 constructs in Figure 4-21.

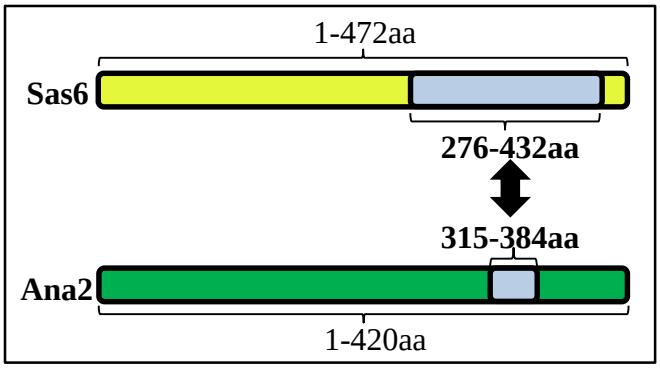

Figure 4-24 Summary of the findings of *in vitro* interaction studies: The Plk4-phosphorylated Ana2-STAN motif (blue, aa315-384) directly interacts with the Sas6 region aa276-432 (blue).

4.3 Discussion

This chapter focuses on the protein kinase Plk4 and the centriole duplication proteins Ana2 and Sas6. It elucidates their interaction, phosphorylation, dependencies, and strikingly describes their function in the initial steps of procentriole formation. The performed work results in the major centriole duplication related finding, that Plk4-mediated phosphorylation of the conserved STAN motif in Ana2 triggers its interaction with the cartwheel protein Sas6 and enables procentriole formation in *Drosophila*. This new knowledge is one further piece towards understanding the puzzle of the timely link of centriole duplication to only once per cell cycle in order to maintain correct centrosome numbers.

Initial protein interaction studies show that bacterial expressed and purified Plk4 and Ana2 interact directly with the ^{35}S-Methionine-labelled counter protein, expressed in an *in vitro* transcription-translation system, in *in vitro* interaction assays (section 4.2.1.1, Figure 4-1). In contrast, the cartwheel protein Sas6 does not interact with Plk4 or Ana2 in direct *in vitro* interaction assays (section 4.2.1.1, Figure 4-2). Plk4 is described as the master kinase of centriole duplication, as its overexpression induces centriole duplication in cell culture and *de novo* centriole formation in *Drosophila* unfertilized eggs, and depletion of Plk4 causes loss of centrosomes [83–85,96,289]. Plk4 is recruited to the centriole by Asterless [92] but little is known about Plk4 and its substrates in the centriole duplication process. It is known from *C. elegans*, that Sas5 and Sas6 are recruited to the centriole after the recruitment of Zyg-1 [53,91], the Plk4 homologue. This suggests that the *Drosophila* homologues Ana2 and Sas6 might be recruited in a similar timely manner. The finding in section 4.2.1.1, that Plk4 and Ana2 interact directly with each other *in vitro* supports this idea. In *C. elegans*, Sas5 and Sas6 are recruited simultaneously and co-dependently to form the central tube, which then further enlarges with the recruitment of Sas4. But the exact molecular mechanism of the Sas5 and Sas6 interaction is still not fully understood. It is suggested that the C-terminal Sas5 domain (aa390-404) interact with a narrow region in the Sas6 coiled-coil domain (aa275-288) [302]. And additionally, that the N-terminal domain of Ana2 (aa82-260) forms a tetramer, which

then connects four Sas6 homodimers in two neighbouring rings of the central tube [304] (Figure 4-25). Importantly, the direct and phosphorylation-independent interaction of Zyg-1 with the Sas6 coiled-coil domain results in the recruitment of the Sas6-Sas5 complex to the mother centriole [15]. Both these findings from *C. elegans* differ to the findings observed and described here, where *Drosophila* Sas6 does not directly interact with Plk4 or Ana2 *in vitro* (section 4.2.1.1, Figure 4-2).

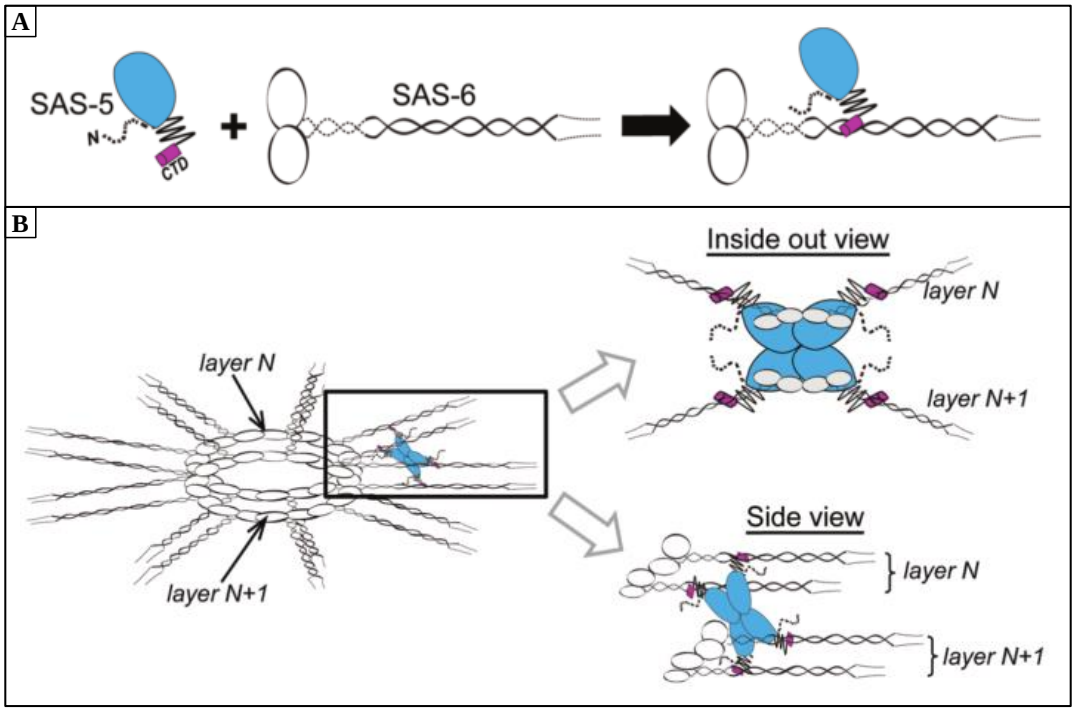

Figure 4-25 Schematic model how *C. elegans* Sas5 and Sas6 might interact to form the central hub of the centriole. (A) shows a Sas5 molecule interact with a central region of a Sas6 homodimer. Figure from [304] and as previously reported in [302]. (B) shows a model how tetrameric Sas5 could interact with two Sas6 homodimers from two neighbouring rings each in the central hub assembly of *C. elegans*. Figure reproduced with permission from [304].

The analyses of centriole duplication proteins and their possible role as phosphorylation substrates of Plk4 go in line with the direct interaction results. Two versions of Plk4 are used in the performed phosphorylation assays, firstly, an active form of Plk4 (MBP-Plk4-T172E), which has auto-phosphorylation activity, and secondly a kinase dead form of Plk4 (MBP-

Plk4-T172E-K43M). The phosphorylation activity of MBP-Plk4-T172E was shown by bandshift on SDS-PAGE due to auto-phosphorylation of the protein in comparison to the kinase dead Plk4 form (section 4.2.1.2, Figure 4-3). Additionally, treatment of active Plk4 with lambda-phosphatase, which releases phosphate groups from phosphorylated Serine, Threonine and Tyrosine residues, reverses the bandshift to the motility seen by kinase dead Plk4, confirming that MBP-Plk4-T172E is active and can phosphorylate (section 4.2.1.2, Figure 4-3). Phosphorylation assays with N-terminal MBP-tagged Ana2 and Sas6 (section 4.2.1.2, Figure 4-4) and N-terminal GST-tagged Ana2 (section 4.2.1.2, Figure 4-5) show that Plk4 phosphorylates MBP- and GST-N-terminal tagged Ana2 but not MBP-Sas6. The finding of Ana2 phosphorylation by Plk4 but the lack of Sas6 phosphorylation by Plk4 is incomparable to findings in *C. elegans* and human cells. In *C. elegans*, the Plk4 homologue Zyg-1 recruits Sas6 in a phosphorylation-independent manner, which in turn is in a pre-formed complex with Sas5, the Ana2 homologue [15]. However, it was previously described that Sas6 is phosphorylated by Zyg-1 at S123, and that this phosphorylation is crucial for centriole formation *in vivo* and it ensures the maintenance of Sas6 at the procentriole [113]. On the other hand, two publications show that the Serine/Threonine protein phosphatase 2A (PP2A) regulates Sas5 recruitment to the centriole. It is suggested that phosphorylation of Sas5 inhibits its recruitment to the procentriole [119] or that phosphorylation of Sas5 promotes its destruction [305]. However, neither publication show evidence for which kinase phosphorylates Sas5 in the first instance. It was suggested that Zyg-1 kinase regulates Sas5 association with the centrioles because *zyg-1* mutant embryos show normal cytoplasmic levels of Sas5 but lack centriolar localisation of Sas5 [72]. In summary, the *C. elegans* Sas5-Sas6-complex is positively regulated by a combination of PP2A dephosphorylating Sas5 and the Zyg-1 kinase phosphorylating Sas6. Presumably this is also the order of events, as PP2A does not localise to the centriole whereas Zyg-1 does. Additionally, at the time of my experiments, there had been no published evidence about the Plk4 phosphorylation of STIL or Sas6, the human homologues of Ana2 and Sas6. In summary, the phosphorylation of *Drosophila* Ana2 by Plk4 but on the other hand the lack of Sas6 phosphorylation by Plk4 is an intriguing new observation.

It is important to understand the phosphorylation of Ana2 by Plk4 and the potential role of this phosphorylation in centriole duplication, thus all Plk4 phosphorylation sites were identified by phospho-peptide mapping by mass spectrometry (section 4.2.2, Table 4‑1). Samples for analyses were either purified ProteinA-Ana2 from cultured *Drosophila* cells co-expressing non-degradable Plk4 or *in vitro* phosphorylated GST-Ana2 protein. The highest spectral counts identified *in vitro* and *in vivo* were S318 and S365/S370/S373. Further but weaker Plk4-phosphorylation sites are present in Ana2-N-terminus (section 4.2.2, Figure 4-6). The dominance of phosphorylation sites in the Ana2-C-terminus (aa281-420) is confirmed by the phosphorylation assay (section 4.2.2, Figure 4-8), which shows a stronger phosphorylation signal for C-terminal Ana2 than for N-terminal Ana2 (aa1-280). The significance of the phosphorylation of Ana2 in its C-terminal part suggests an evolutionary conserved region within Ana2. Ana2 does not exhibit a strong sequence homology between species and only recently has *Drosophila* Ana2 been identified as the functional orthologue of *C. elegans* Sas5 [116] and of human STIL. This is despite STIL having been described in connection with T-cell acute lymphoblastic leukaemia as early as 1991 [306] and more recently as being defective in primary microcephaly [307]. Structural similarities between Sas5, Ana2 and STIL exist; all proteins have a predicted central coiled-coil domain, a TIM motif at the most C-terminus (aa407-420 in *Drosophila*) [117] and most significantly a STAN motif localised in their C-terminal regions. A homology alignment of the STAN motif regions of different species confirms the high significance of the identified Plk4 phosphorylation sites S318, S365, S370 and S/T373 in Figure 4-7, as they are conserved between species. Due to the high spectral count of the four Serine sites in *Drosophila* Ana2 (section 4.2.2, Table 4‑1), the visually high Plk4-phosphorylation of Ana2-C-terminus compared to Ana2-N-terminus *in vitro* (section 4.2.2, Figure 4-8), and the conservation of these sites throughout different species (section 4.2.2, Figure 4-7), my focus was upon the further characterisation of Ana2 and its Plk4-phosphorylation on S318, S365, S370 and S373 to determine their functional role in centriole duplication.

The role of Ana2/Sas5/STIL in centriole duplication, structure and centrosome numbers is of great interest and its role is starting to emerge. The importance of Ana2 in centriole duplication is confirmed in section 4.2.3.1 (Figure 4-9) because its depletion via RNA-interference in cultured *Drosophila* cells leads to loss of centrosomes. The experiment shows the effect on centrosome numbers after depletion of Ana2 protein by two different dsRNAs against coding sequence (CDS) of Ana2 and the untranslated regions (UTR) of Ana2. After three rounds of depletion for 4 days each, the cells show a significant loss of centrosomes compared to the negative control (GST RNAi), with approximately 94.3% and 67.7% of cells lacking centrosomes after *Ana2 CDS* RNAi and *Ana2 UTR* RNAi respectively. The described inability to duplicate centrioles after Ana2 depletion was also observed in *C. elegans* [23] and human cells [41,117,118], after depletion of Sas5 and STIL respectively. Interestingly, the loss of centrosomes after Sas5 and STIL depletion is comparable to the observed loss of centrosomes after depletion of Plk4 and Sas6 [85,288]. Additionally, inactivation of Sas5 in *C. elegans* causes failure of centrosome duplication at the two-cell stage embryos [308], which is also the observed phenotype in embryos deprived of Zyg-1 [22] or Sas4 [16,20]. Taken together, this confirms the importance of Ana2 in centriole duplication.

Additionally, the results in Figure 4-9 show that Ana2 can be efficiently depleted by its UTR regions. In turn, this allows the specific targeting of endogenous Ana2 in cells expressing transgenic Ana2, with the latter not carrying UTR sequences. This method was applied in section 4.2.3.2, where cultured *Drosophila* cells expressing transient Ana2-4A or Ana2-4D were depleted of endogenous Ana2 by *UTR* RNAi in rescue experiments. Ana2-4A and Ana2-4D carry mutations at aa318, aa365, aa370 and aa373, with a Serine to Alanine mutation or a Serine to Aspartic acid mutation respectively, and represent non-Plk4-phosphorylatable and phospho-mimicking Ana2 constructs respectively. They were used to analyse the importance of the Plk4 phosphorylation of Ana2 at these residues (identified in section 4.2.2, Table 4–1) for centrosome numbers and therefore for centrosome duplication. The expression of transgenic Ana2-4D mutant rescues centrosome numbers after the depletion of endogenous Ana2 with a weak negative effect compared to cells treated with control GST RNAi (section 4.2.3.2, Figure 4-10 and Figure 4-11). This result is similar to that

observed in cells expressing transgenic Ana2-WT after depletion of endogenous Ana2 (section 4.2.3.2, Figure 4-10 and Figure 4-11). On the other hand, cells expressing the transgenic Ana2-4A mutant were not able to rescue centrosome numbers after depletion of endogenous Ana2, as approximately 83.5% of cells exhibit no centrosomes after three rounds of RNAi (section 4.2.3.2, Figure 4-10 and Figure 4-11). The centrosomes were immune-stained using specific antibodies against D-Plp and Asterless, and centrosomes were counted. Cell lines expressing Ana2-WT and Ana2-4D, showed centrosomal co-localisation of Asterless and D-Plp after the depletion of endogenous Ana2 (section 4.2.3.2, Figure 4-11). Whereas cells that expressed transgenic Ana2-4A lacked centrosomal signals of Asterless and D-Plp (section 4.2.3.2, Figure 4-11). In summary, Ana2-4A, the transgenic construct that cannot be phosphorylated by Plk4 at residues aa318, aa365, aa370 and aa373, cannot support centriole duplication. Whereas Ana2-4D, which mimicks Plk4-phosphorylation, rescues centrosome numbers. In summary, the kinase activity of Plk4 in phosphorylating the four Serine residues in Ana2 (S318, S365, S370, S373) is important in the regulation of centriole duplication.

But how does the Plk4-phosphorylation of Ana2 affect centriole duplication? Is Ana2 phosphorylation directly necessary for its recruitment to the centrosome? Or does it change the accessibility of Ana2 protein for recruitment? And what function does the interaction of Plk4 and Ana2 serve compared to Ana2 phosphorylation? After all, Zyg-1 is recruited by Spd2 as the first protein to the procentriole in *C. elegans* [53,91], and it was observed in *Drosophila* that Plk4 is recruited by Asterless [92], and in human cells by the homologues of Spd2 and Asterless (Cep192 and Cep152 respectively) [93,294,309]. This raises the question of whether the phosphorylation of Ana2 in fact triggers a more downstream process in centriole duplication? In *C. elegans*, Sas5 and Sas6, the Ana2 and Sas6 homologues, form a Sas5-Sas6 complex before being recruited to the procentriole [114]. Therefore, I developed in collaboration with Dr. Lipinszki a phosphorylation and binding assay that enables the direct interaction of Sas6 with Plk4-phosphorylated Ana2 to be tested *in vitro* (section 2.8.3). The difficulties in designing this assay lay in the generation of protein reagents that can be used

in combination but without unspecific binding; and to sustain the Plk4-phosphorylation state of Ana2, but still allow for direct protein interaction assays/pull-downs and washes. The finalised *in vitro* phosphorylation-binding-assay was then applied to treat GST-Ana2 and GST-Ana2-4A (on resin) with active MBP-Plk4 or kinase-dead MBP-Plk4^{KD}, followed by a direct binding assay with ^{35}S-Methionine-labelled Sas6 protein (section 4.2.4, Figure 4-15 left panel). Excitingly, this identified Sas6 as a direct binding partner of Plk4-phosphorylated Ana2 *in vitro*. This observation is highly significant in the understanding of the role of Ana2 in the *Drosophila* centriole duplication process. I previously showed that Sas6 does not interact directly with Ana2 in a direct binding assay *in vitro* (section 4.2.1.1, Figure 4-2). Moreover, the treatment of GST-Ana2 with kinase-dead Plk4, and GST-Ana2-4A with active and kinase-dead Plk4 in phosphorylation-binding-assays resulted in no interaction of Sas6 with Ana2. Thus, the phosphorylation of GST-Ana2 at S318, S365, S370 and S373 by active Plk4 triggers the interaction of Sas6 with Ana2. A potential physical interaction of Ana2 with Plk4 is not the trigger, as Ana2-4A does not interact with Sas6 independent of treatment with active or kinase-dead Plk4. Thus, the interaction of Sas6 and Ana2 is dependent on Plk4-phosphorylation of the four Ana2 Serine residues S318, S365, S370, and S373.

There are multiple hypotheses of how Plk4-phosphorylation of full-length Ana2 permits for its interaction with Sas6. Firstly, the phosphorylation state of the four conserved Serine residues in the Ana2-STAN motif might directly allow Sas6 to bind a region containing these phosphorylation sites. Secondly, phosphorylation of the Ana2-STAN motif might cause a conformational change which makes a more N-terminal Ana2-region accessible for Sas6 to bind. Thirdly, as seen in Table 4–1 and Figure 4-8, the N-terminal region of Ana2 is lightly phosphorylated by Plk4, which could contribute to Sas6 binding to Ana2-C-terminus. Therefore, I wished to know which region of Ana2 interacts with Sas6; and treated N-terminal Ana2 (aa1-280) and C-terminal Ana2 (aa281-420) with active and kinase-dead Plk4 and tested for their direct interaction with Sas6 *in vitro* (section 4.2.4.1, Figure 4-13). Significantly, only the Plk4-phosphorylated Ana2 C-terminal region was able to bind Sas6 directly, as seen for Plk4-phosphorylated full-length Ana2 (Figure 4-15 left panel). The N-terminal part of Ana2 does not appear to contribute to the interaction with Sas6, as it does

not interact with Sas6 nor does its absence reduce the efficiency of the Plk4-phosphorylated C-terminal part of Ana2 to interact with Sas6.

That the interaction of Plk4-phosphorylated Ana2 and Sas6 is not an artefact observed only *in vitro* is suggested by the complementary co-immunoprecipitation of the two parts from extracts of living cells (section 4.2.4, Figure 4-12, in collaboration with Dr. Lipinszki). Two versions of Ana2 (FLAG-Ana2-WT and FLAG-Ana2-4A) were stably co-expressed with non-degradable or non-degradable kinase-dead Plk4, and transiently expressed Sas6-Myc. FLAG-co-immunoprecipitation revealed that only Plk4-phosphorylated Ana2 was able to interact with Sas6 protein, as observed *in vitro*. This strongly confirms the *in vitro* findings and highlights how important Plk4-mediated phosphorylation of Ana2 is for the very specific and triggered interaction with the cartwheel protein Sas6 and therefore for centriole duplication as a whole. The significance of the above finding is surprising, as nothing similar has been described for their homologues. In *C. elegans*, Sas5 and Sas6 are suggested to be present as individual oligomers, which change confirmation when they form a hetero-Sas5-Sas6-complex and that the interaction between Sas5 and Sas6 is based on synergistic hydrophobic and electrostatic interactions [302].

After identifying that the specific four Serine residues (S318, S365, S370, S373) in the Ana2 STAN motif must be phosphorylated by Plk4 to trigger interaction with Sas6, it raises the question of the importance of each individual Serine residues for Ana2-Sas6 interaction. Is the phosphorylation of a single site efficient to trigger the specific interaction? Or is phosphorylation of all four Serine residues required? The analyses of Sas6's interaction with four individual Ana2 mutant constructs, each carrying a Serine to Alanine mutation at each of the four conserved Serine residues, suggests that all four Serine residues must be phosphorylated by Plk4 to enable a strong interaction of phosphorylated Ana2 with Sas6 (section 4.2.5, Figure 4-15). Significantly, none of the four analysed Ana2 constructs were able to interact as strongly as Ana2-WT with Sas6 but neither did any of the point mutations fully abolish interaction of Ana2 with Sas6. However, the mutation of Ana2-S370A reduces the interaction with Sas6 to a greater extent than the other Ana2 mutants, suggesting that

Plk4-phosphorylation of S370 is of particular significance for the interaction of Ana2 with Sas6. Nevertheless the loss of any one of the four Plk4-phosphorylation sites within the Ana2 STAN motif reduces its efficiency to interact with Sas6; and the interaction does not depend upon any single phosphorylation site.

Similarly, the C-terminal part of Ana2 (aa281-420) binds as efficiently to Sas6 as full-length protein (section 4.2.5.1, Figure 4-16). Significantly, also a triple mutant of Ana2-C-3A, which only retains the phosphorylatable S318 but carries Serine to Alanine mutations for aa365, aa370 and aa373, does not prevent binding of Sas6 fully (section 4.2.5.1, Figure 4-16). But Plk4-phosphorylated Ana2-C-3A shows a more significantly reduced interaction with Sas6 than any of the four individual Serine mutants of Ana2-C. All four conserved Serine residues in the Ana2-STAN motif must be phosphorylated by Plk4 to trigger efficient interaction with Sas6 and mutation in any one reduces but does not abolish binding.

Reciprocally I showed that the Ana2-4D mutant, which mimicks phosphorylation of Ana2 at S318D, S365D, S370D and S373D, interacts with Sas6 independently of treatment with active or kinase dead Plk4 (section 4.2.6, Figure 4-17). The strength of interaction is comparable to the interaction of Plk4-phosphorylated Ana2-WT with Sas6 accounting for the ability of Ana2-4D to rescue centriole duplication after depletion of endogenous Ana2 in *Drosophila* cell culture with similar efficiency as transgenic Ana2-WT (section 4.2.3.2, Figure 4-10 and Figure 4-11). That a phospho-mimicking Ana2 mutant (Ana2-4D) interacts with Sas6 confirms the findings that the four Serine residues in the Ana2-STAN motif are crucial and that their phosphorylation by Plk4 is the trigger for the interaction of Ana2 with the cartwheel protein Sas6.

The identification of a specific phosphorylation mechanism by which Sas6 is recruited raises the question whether Ana2-phosphorylation is also necessary to trigger further downstream interactions with other centrosomal proteins. To address this, I generated ^{35}S-Methionine-labelled proteins known to be found at centrioles, namely Sas4, Bld10, Rcd4 and Ana1

(section 4.2.7, Figure 4-18). The latter two do not interact with Ana2, not in Ana2's Plk4-phosphorylated nor non-phosphorylated state, whereas Sas4 interacts strongly with Ana2, and Bld10 increases its interaction when Ana2 is Plk4-phosphorylated.

Rcd4 is a protein identified in a genome-wide RNAi screen for centrosome defects, which localises to the centrosome and was categorised as functioning in centriole duplication and/or efficient PCM recruitment [131]. The *Drosophila* protein does not have any known homologues and to date, there have not been any further published studies on Rcd4.

Ana1 represents one of the three Ana proteins suggested to be involved in centriole duplication. So far, the research undertaken on the protein is limited. But it is known that Bld10, Ana1 and Asterless are recruited sequentially in the centriole-to-centrosome conversion [30] and that after depletion of Plk4, Ana1 no longer localises to the centrosome. Additionally, Ana1 depletion leads to a highly reduced signal of Sas6 at the spindle poles [310]. This suggests, that Plk4 is required for Ana1 recruitment to centrioles and that Ana1 acts downstream of Plk4. Conversely, Ana1 is recruited to the centriole upstream of Sas6. But Sas6 does not seem required for Ana1 recruitment to centrioles but might play a role in the maintenance of Ana1 at the centriole.

Sas4, a centriole protein essential for microtubule recruitment, interacts strongly with Ana2 independently of Plk4-phosphorylation. That Sas4 interacts with Ana2, regardless of Ana2's phosphorylation state, is in line with the interaction of CPAP and STIL, the human orthologues of Sas4 and Ana2 respectivelly. The analysis of their crystal structure defined their interaction interface to be the STAN motif of STIL and the C-terminal G-box of CPAP, and significantly, mutations within this interface disturbs centriole duplication *in vivo* [41,42,44]. Depletion of STIL interfered with CPAP recruitment to the procentriole and centriole elongation, but reciprocal, depletion of CPAP did not affect targeting of STIL to the centriole, suggesting that STIL recruitment to the centriole occurs upstream and is independent of CPAP [41]. Significantly, overexpression of Sas4 causes rapid *de novo* formation of centriole-like structures in approximately 60% of unfertilized *Drosophila* eggs, which normally do not have centrioles [96]. Moreover, overexpression of Sas4 does not lead to extra centriole-like structures in brain cells nor spermatocytes [96]. The major role of Sas4 at the centriole is in

recruitment and/or maintenance of microtubules, as depletion of *C. elegans* Sas4 prevents these processes [53]. Moreover CPAP overexpression causes very long centrioles [38,39]. More research needs to be undertaken to further understand how Sas4 and Ana2 interact with each other and how this affects centriole duplication in *Drosophila*.

Interestingly, Bld10, which is known to maintain centriole structure but is not essential for centriole duplication in *Drosophila* [65], interacts with non-phosphorylated Ana2 but this interaction is stronger when Ana2 is Plk4-phosphorylated. The strength of interaction of the latter is comparable to the interaction strength of Sas6 with Plk4-phosphorylated Ana2. Bld10 protein is conserved amongst organisms that have centrioles, and has homologues in *C. elegans* and human cells; Bld10p and Cep135 respectively [32]. Bld10p and Cep135 are essential for centriole formation in *Paramecium*, *Tetrahymena* and human cells but not so in *Drosophila* [43,65,73,311,312]. *Drosophila* mutants that lack Bld10 assemble cartwheels and centrioles, although the cartwheel appears to be wider and unstable [32,64–66]. In contrast, *Chlamydomonas* Bld10 forms the distal part of the cartwheel spoke and contributes to their proper length [62]. Additionally, Bld10p/Bld10/Cep135 are microtubule-binding proteins [43,68], which suggests they might nucleate and/or stabilize microtubules at the transition zone of cartwheel spokes to microtubules. Details of the molecular interaction of Ana2 and Bld10 and its function is currently unknown but it is possible to speculate that Ana2 might recruit Bld10 to the centriole or that Ana2 could stabilise the cartwheel and microtubules via Bld10. The increase in binding of Bld10 to phosphorylated Ana2 could be a mechanism that times Bld10's association with the centriole or to license Bld10 to interact with other proteins of the cartwheel or centriole.

Structural homology studies of Ana2/STIL reveal that the protein has two conserved C-terminal motifs: the STAN motif and the TIM motif at the very C-terminus [117], with the latter being truncated in microcephaly patients [307]. The C-terminal part of Ana2 contains both of these motifs. However, my studies subsequently showed that the STAN motif alone is efficient for phospho-dependent binding to Sas6 which does not depend on the TIM motif (Figure 4-20). This is in line with observations of microcephaly mutants of STIL, which lack

the C-terminal TIM motif and cannot be degraded but remain a normal STIL function [307]. It also confirms the high importance of the Ana2-STAN motif in cartwheel assembly and centriole biogenesis.

My phosphorylation and binding assays show that Sas6 aa276-432 is the smallest region able to interact with Ana2 (section 4.2.8.2). We do not know the structure of the entire protein Sas6. However, crystallographic studies of Sas6 homologues have elucidated the 3D structure of the N-terminal head domain and the N-terminal part of the coiled-coil domain [63,69,74,75]. These studies show that Sas6 has an N-terminal head domain, which forms the inner cartwheel hub and a coiled-coil domain which dimerises to form the cartwheel spokes, and an unstructured C-terminal end. However, the structure of the whole coiled-coil domain and particularly the C-terminal region, which could be part of the cartwheel spokes that connect microtubules, is not known. It is intriguing that this C-terminal region of Sas6 interacts with Ana2-STAN, as it localises Ana2 function to the outer cartwheel region. This is significant in the light of observations in human cells, where STIL interacts directly with CPAP, and in the case of STIL or Sas6 depletion where CPAP fails to localise to the nascent procentriole [41]. The identification of the interacting regions between Ana2 and Sas6 needs further analysis at atomic resolution, to determine the precise structural interaction and how this might affect centriole duplication. This presents a big challenge. To show this, it will be necessary to overcome lack of solubility of the proteins and fragments of the proteins for crystallisation trials; and their stoichiometry, as we know that both proteins form homodimers giving the potential for change in stoichiometry when the proteins interact. To fully understand precisely how Ana2 and Sas6 interact, it will be necessary to overcome these difficulties to gain further insight.

Chapter 5

The novel direct interaction and centrosome localisation of Dragon (CG33052) with the cartwheel protein Sas6

5 The novel direct interaction and centrosome localisation of Dragon (CG33052) with the cartwheel protein Sas6

5.1 Introduction

In this chapter I will explore the interactions of Sas6 with a second protein that we have called Dragon (CG33052) that to date has not been studied in *Drosophila*.

We identified the *Drosophila* homologue Dragon as a partner of the centrosomal protein Sas6 following its affinity purification from *Drosophila* cell culture. My objective in this chapter was to understand its interaction with centriolar proteins and its potential role in centriole duplication. Specifically, I wanted to determine if there is a direct protein-protein interaction between Dragon and the centrosomal cartwheel protein Sas6. If so, what are the structural and interaction characteristics of this potential interaction, where does Dragon localise, and what effect does depletion of Dragon have on centrosome numbers?

5.2 Results

5.2.1 Identification of Dragon, a Golgi protein in complex with the centrosomal protein Sas6

5.2.1.1 *In vivo* purifications of Sas6 reveal the novel Golgi protein Dragon in complex

As part of a study of the interactions made by centrosomal proteins, different centrosomal proteins were purified from *Drosophila* cell culture and *Drosophila* syncytial embryos, and subjected to mass spectrometry analyses. My particular interest was in Sas6, which is known to form the inner hub and cartwheel structure of centrioles and is one of the first proteins detected at the site of daughter centriole formation on the mother centriole. In chapter 4, I show phosphorylation of Ana2 by Plk4 at its STAN motif triggers direct interaction of Ana2 with Sas6 and recruitment to the site of procentriole formation. In the analyses of Sas6 assosiated proteins purified from *Drosophila* cell culture and syncytial embryos, we repeatedly observed the previously uncharacterised protein CG33052 in *Drosophila*. From here onwards CG33052 will be refered to as Dragon. Table 5-1 summarises the Mascot 'scores' and 'number of peptides' identified by mass spectrometry for Sas6 and Dragon, purified from cultured *Drosophila* cells and *Drosophila* syncytial embryos (complete lists in Appendix C). *Drosophila* cells were stably transformed with pMT-PrA-Sas6 and expression of PrA-Sas6 was induced with 1mM $CuSO_4$ for 22 hours. As indicated, cells were treated with 25µM MG132 for up to 5 hours to inhibit proteasomal degradation and/or 50nM okadaic acid for 9 to 16 hours to inhibit protein phosphatases. Sas6 was also expressed constitutively in *Drosophila* syncitial embryos (aged 0-4 hours) derived from *poly-Ub-Sas6-GFP* expressing flies. During the purification of Sas6, high NaCl (440mM) concentrations and 50nM okadaic acid were included in the elution and wash buffer, as indicated (Table 5-1B).

The Sas6 bait exhibited high Mascot ‘scores‘ and large ‘number of identified peptides‘ in all analysed samples, suggesting successful enrichment of Sas6 protein from *Drosophila* cell cultures and embryos. The samples from cultured *Drosophila* cells consistently revealed Dragon in complex with the bait protein Sas6. Dragon was present with high Mascot scores in the purifications from syncytial embryos, independently of whether okadiac acid treatment was given. A high 440mM NaCl concentration in the elution and wash buffer led to lower Mascot scores of Dragon compared to the samples treated with the usual 150mM NaCl concentration. Control purifications of PrA or GFP expressed alone do not identify Dragon. Purification of Dragon with consistantly high scores when Sas6 was purified from either *Drosophila* cell culture or syncytial embryos suggests that Dragon is a true member of a complex with the centrosomal protein Sas6 *in vivo*.

Table 5-1 Sas6 protein purification and mass spectrometry analyses from *Drosophila* cell culture and *Drosophila* syncytial embryos reveal Dragon protein in a complex with Sas6. Sas6 protein was purified from *Drosophila* cell culture expressing pMT-PrA-Sas6 (treated with and without okadaic acid), and from *Drosophila* syncytial embryos expressing poly-Ubiquitin-Sas6-GFP (treated with and without okadaic acid, high salt equals 440mM), followed by mass spectrometry. The tables summarise the presence of Sas6 and Dragon in complex and their according number of peptides in the samples (*purifications in student projects). OA: okadaic acid. Complete lists in Appendix C.

A *Drosophila* cell culture

Sas6	4677	131
Dragon	1380	27

5.2.1.2 *In vivo* purifications of Dragon confirm Sas6 in complex

To further confirm that Sas6 and Dragon form in complex *in vivo*, I performed the reciprocal experiment; to analyse whether GFP-tagged Dragon co-purifies with Sas6. To this end, I established cell lines for inducible Dragon-GFP and constitutively expressed GFP-Dragon, and affinity purified these proteins from *Drosophila*. Dragon protein purified from *Drosophila* cell culture was analysed by mass spectrometry (complete lists in Appendix C). All samples showed high bait Mascot scores for Dragon between 16669 to 61897 (253 to 766 peptides), giving a high protein coverage of 62 to 74%. Sas6 protein was identified as the only centriole duplication protein by mass spectrometry in all analysed purifications (Table 5-2A). But co-purified Sas6 seems to be positively affected or stabilised if the Dragon bait is constitutively expressed rather than induced, Dragon is N-terminally tagged rather than C-terminally and the cells were treated with okadaic acid. Significantly, Sas6 was identified as the top scoring protein and the only centriole duplication protein purified with Dragon from syncytial *Drosophila* embryos (Table 5-2B). Though common contaminants were Heat shock protein cognate 4 CG4264 and Elongation factor 1α48D CG8280 (for full list see Appendix C), which are often found in control purifications. The GFP-trap binding was performed for 2.5 hours to allow for efficient purification of Dragon protein in complexes, including potentially less represented complexes within the sample. Mass spectrometry identified the bait Dragon with a score of 2764 (50 peptides, giving a protein coverage of 71%). On the other hand, Sas6 was identified in complex with Dragon at a score of 752 (18 peptides, 44% protein coverage). Thus, confirming that Dragon and Sas6 co-purify in complex *in vivo* from cultured *Drosophila* cells as well as directly from *Drosophila* syncytial embryos.

Table 5-2 Purifications of Dragon reveal it is in complex with Sas6 *in vivo*. Dragon protein, purified from A) *Drosophila* cell culture expressing poly-Ubiquitin-GFP-Dragon or pMT-Dragon-GFP (treated with and without okadaic acid) and B) from *Drosophila* syncytial embryos expressing poly-Ubiquitin-GFP-Dragon. Mass spectrometry reveals that Sas6 is in complex with Dragon. Number of peptides and the peptide coverage for Dragon and Sas6 are indicated for each sample. Complete lists in Appendix C.

5.2.1.3 *In vivo* purifications of Dragon confirm COPI subunits in complex

In addition to the centrosomal cartwheel protein Sas6 in complex with Dragon (section 5.2.1.2), the majority of the subunits of the Golgi COPI proteins were present in Dragon purifications from *Drosophila* cell culture (Table 5-3). The subunits αCOP, β'COP and εCOP of the cage-like subcomplex of COPI and the subunits γCOP and βCOP of the adaptor subcomplex of COPI were present in all samples. The εCOP subunit of the cage-like

subcomplex was present in all purifications but one. Hence, all three subunits of the cage-like subcomplex (α-β'-ε-COPs) are present in the Dragon purifications. On the other hand, the subunits δCOP and ζCOP were not identified. Thus, only two out of the four subunits of the adaptor subcomplex of COPI are present in Dragon purifications. No COPI subunits were found in GFP control purifications or in complex with purified Sas6. Thus COPI subunits appear to associate specifically with the Dragon bait. Additionally, CtBP (C-terminal binding protein), which was suggested to function as a transcriptional co-repressor [313–317], was highly represented in complex with Dragon in all four Dragon purifications from *Drosophila* cell cultures and apparently in higher quantity in cells treated with okadaic acid. This suggests that the inhibition of dephosphorylation by PP2A stabilises CtBP in complex with Dragon.

Table 5-3 Purifications and mass spectrometry analyses reveal subunits of COPI and CtBP in complex with Dragon. Dragon protein, purified from *Drosophila* cell culture expressing poly-Ubiquitin-GFP-Dragon or pMT-Dragon-GFP (treated with (+OA) and without okadaic acid), followed by mass spectrometry show CtBP and five out of seven known COPI subunits in complex with Dragon. Highlighted in pink are the COPI subunits forming the cage-like subcomplex (α-β'-ε-COPs), and in blue the COPI subunits forming the adaptor subcomplex (γ-β-δ-ζ-COPs). When present in the purification sample, the Mascot 'scores' and 'number of peptides' are stated for Dragon, CtBP and each subunit of COPI.

5.2.2 Localisation of Dragon at the centrosome and Golgi

5.2.2.1 Dragon co-localises to the centrosome with Sas6

The human counterpart of Dragon is the protein GoRab that is reported to function at the Golgi and its vesicles [202,214–216]. Thus the purification of Dragon in complex with the centrosomal protein Sas6 from *Drosophila* was unexpected. I therefore asked whether Dragon localises with Sas6 at the centrosome. Therefore, I performed immune localisation studies to determine whether Dragon-GFP or myc-Dragon, stably expressed in cultured *Drosophila* cells, would allocate with the centrosomal marker D-Plp. This revealed co-localisation of D-Plp with GFP- and myc-Dragon at the centrosome (Figure 5-1), and also GFP- and myc-Dragon at the Golgi structure (this is further explored in section 5.2.2.2). I then set out to determine the position of Dragon related to Sas6 at the centrosome by structured illumination microscopy in collaboration with Dr. Tzolovsky. *Drosophila* wild-type cells were stained with antibodies against Dragon, Sas6 and D-Plp, followed by imaging and analysis. These images confirmed that Dragon localises to the centrosome and more specifically to zone 1 with the centrosomal cartwheel protein Sas6 within the D-Plp ring (Figure 5-2). D-Plp allows the mother and daughter centriole to be distinguished. D-Plp forms a ring-like structure at the centrosome during the whole cell cycle, and the daughter centriole matures by recruiting D-Plp in a ‘horn’-like pattern which develops into a ring-like structure by meta-/anaphase. Sas6 and Dragon co-localise to the inner space of the D-Plp ring (zone 1), corresponding to the mother centriole, throughout the whole cell cycle. Sas6 and Dragon also co-localise as a single dot at the site of procentriole formation. Thus, Sas6 and Dragon co-localise throughout centriole assembly, maturation and separation, and hence are present on both mother and daughter centriole throughout the whole cycle (Figure 5-2). This suggests a simultaneous rather than a sequential recruitment of Sas6 and Dragon.

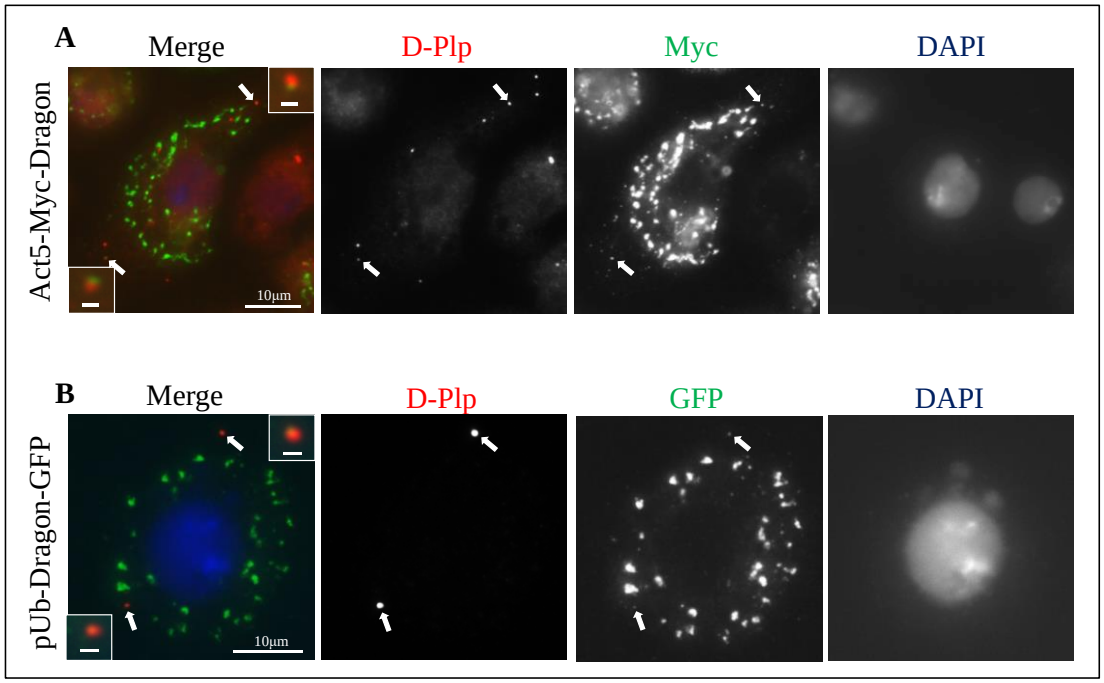

Figure 5-1 Dragon localises to centrosomes in *Drosophila* cell culture. Micrographs show centrosomes revealed by D-Plp and Myc/GFP co-staining in the two *Drosophila* cell lines expressing Act5-Myc-Dragon or pUb-Dragon-GFP; insets show D-Plp and Myc/GFP co-localisation from each pole (indicated by white arrows). Additionally, Myc/GFP stainings reveal Golgi localisation of Dragon in both cell lines (as further explained in Figure 5-3). DNA is stained with DAPI (blue). Scale bars represent 10µm for main image and 1µm for insets.

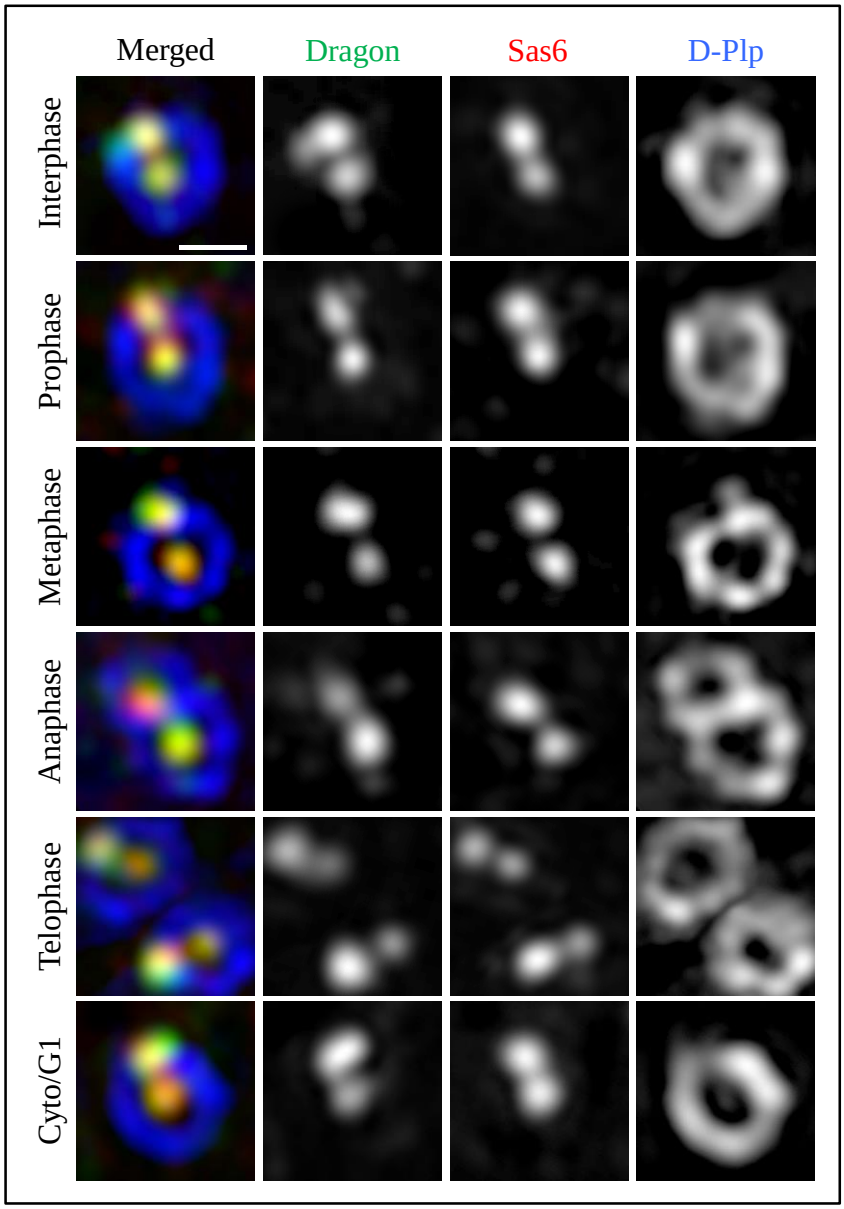

Figure 5-2 Localisation of endogenous Dragon (green) relative to centrosomal Sas6 (red) and D-Plp (blue) throughout the cell cycle. Structured illumination microscopy of endogenous Dragon, Sas6 and D-Plp throughout cell cycle stages in wild type *Drosophila* cell culture. Dragon and Sas6 co-localise at the centre of the D-Plp ring at the mother centriole throughout the cell cycle, as well as at the site of procentriole formation and daughter centriole at the periphery of the D-Plp ring. Scale bar 0.25μm. Microscopy and images by Dr. Tzolovsky.

5.2.2.2 Dragon protein localises to the *trans*-Golgi but not the *cis*-Golgi in *Drosophila* cell culture

As the human homologue of Dragon, GoRab, was reported as a *trans*-Golgi protein [202] I wanted to determine whether *Drosophila* Dragon was also a Golgi protein. In collaboration with Miss Chu I studied *Drosophila* cell culture stably expressing FLAG-Dragon to reveal the FLAG-tag, Golgin-245, GM130 and DAPI, to localise Dragon, the *trans*-Golgi, the *cis*-Golgi and DNA respectively (Figure 5-3) [318,319]. This identified Dragon at the Golgi, where it co-localises with the *trans*-Golgi marker Golgin-245 but not with the *cis*-Golgi marker GM130. Interestingly, this is similar to observations in human cell culture, where the Dragon homologue GoRab co-localises with the *trans*-Golgi protein Rab6 but not with the *cis*-Golgi matrix marker GM130 [202]. Thus Dragon has a dual localisation within cultured *Drosophila* cells; at the *trans*-Golgi and co-localised with Sas6 at the core of the centriole.

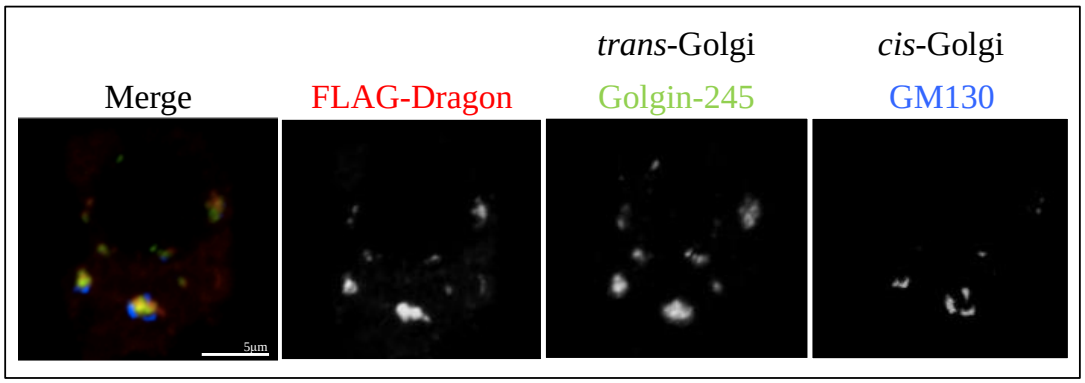

Figure 5-3 Localisation of Dragon to the *trans*-Golgi. Cultured *Drosophila* cells stained to reveal FLAG (Dragon, red), Golgin-245 (green) and GM130 (blue). Dragon co-localises to the *trans*-Golgi with Golgin-245 but not to the *cis*-Golgi with GM130. Scale bar 5µm. Microscopy and images by Miss Chu.

5.2.3 Depletion of Dragon in *Drosophila* cell culture causes loss of centrosomes but Golgi structures are not affected

5.2.3.1 Depletion of Dragon in *Drosophila* cell culture affects centriole duplication and causes loss of centrosomes

A *Drosophila* cells, Dragon CDS RNAi **B *Drosophila* cells, Dragon CDS RNAi 8d**

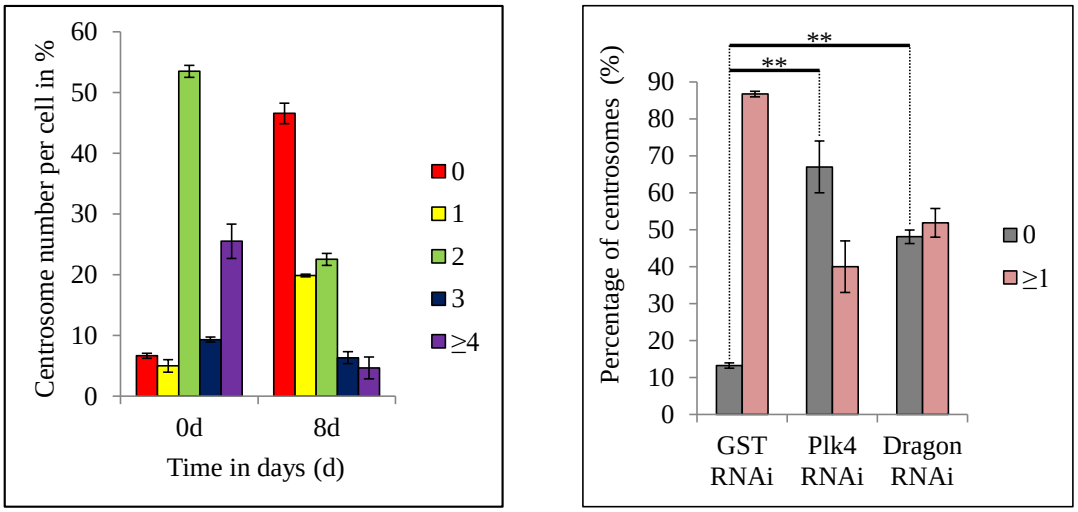

Figure 5-4 Depletion of Dragon by RNAi causes loss of centrosomes in cultured *Drosophila* cells after eight days. A) Numbers of centrosomes per cell are colour coded in the key. (B) Number of cells with zero or with greater and equal than one centrosome per cell after treatment with Dragon dsRNA, GST dsRNA and Plk4 dsRNA. Error bars represent standard error; 3x200 cells counted; significance was calculated by t-test.

As Dragon co-purified and co-localised with Sas6, I wanted to determine whether depletion of Dragon also affected centriole duplication. Therefore, I used RNAi to deplete Dragon from wild-type *Drosophila* cell culture, to study the effect on centrosome numbers. As positive and negative controls, I depleted Plk4 and GST. I performed two 4 day rounds of RNAi and analysed centrosome numbers on day 8. I found that Dragon depletion over this 8 day interval led to loss of centrosomes (Figure 5-4A). The proportion of cells with no centrosomes increased from 6.7% to 46.6%; and with a single centrosome per cell, from 5% to 19.9% after Dragon depletion. This was accompanied by a corresponding decrease in

cells with two centrosomes (from 53.5% to 22.5%); three centrosomes (from 9.3% to 6.3%); and four or more centrosomes (from 25.5% to 4.7%). Dragon depletion was not as effective as Plk4 depletion (46.6% versus 72.2% of cells without centrosomes, Figure 5-4B) but nevertheless suggests a role for Dragon in centriole duplication.

5.2.3.2 Depletion of Dragon does not affect the structure of the Golgi suggesting an alternative role of Dragon at the Golgi

As Dragon co-localises with Golgin-245 at the *trans*-Golgi (section 5.2.2.1) it raised the question whether the Golgi organisation was affected following Dragon depletion by RNAi. Therefore pilot experiments were performed in collaboration with Miss Chu. Cultured *Drosophila* cells were treated with dsRNA against Dragon, Sas6, GFP (negative control), and Plk4 (positive control) for three days. Cells were fixed and stained with antibodies against firstly, D-Plp, Dragon and GM130 for *cis*-Golgi or secondly, against D-Plp, GM130 and Golgin-245 for *trans*-Golgi. These pilot experiments (data not shown) suggest that after control GFP RNAi; D-Plp localised to centrosomes, and Dragon adjacent to the *cis*-Golgi (GM130). After Sas6 or Plk4 RNAi; the centrosomal D-Plp signal was lost, but Dragon and GM130 remained localised at the Golgi. Dragon RNAi led to reduced or absent D-Plp signals at centrosomes, and loss of Dragon from the Golgi, but localisation of GM130 to the *cis*-Golgi and Golgin-245 to the trans-Golgi appeared unaffected by Dragon depletion. Thus, the pilot experiments suggest that depletion of centrosomal proteins Sas6 and Plk4 lead to loss of centrosomes without affecting the localisation of Dragon to the Golgi structure. Additionally, it is suggested that the depletion of Dragon led to loss of centrosomes and loss of Dragon from Golgi. However, the localisation of GM130 and therefore the *cis*-Golgi structure, and Golgin-245 and therefore the trans-Golgi structure do not seem to be structurally affected.

5.2.4 Direct interaction of Dragon and Sas6 confirmed by *in vitro* assays - Identification of binding domains between Dragon and Sas6 *in vitro*

5.2.4.1 The full-length proteins Dragon and Sas6 interact directly with each other *in vitro*

After determining that Dragon and Sas6 exist in a complex *in vivo*; that they co-localise at the centrosome; and that depletion of Dragon protein from *Drosophila* cell culture causes loss of centrosomes, I wished to determine whether Dragon and Sas6 directly interact with each other.

To this end I first expressed full-length GST-tagged Sas6, full-length GST-Dragon and GST-alone in *E. coli*. I purified all of the proteins by binding to Glutathione Sepharose 4B resin via their GST tag (section 2.5.1). Secondly, I synthesised radioactively (^{35}S-Methionine) labelled Sas6 and Dragon protein in coupled transcription-translation reactions. The reactions were performed using the Promega kit TnT® T7 Quick Coupled Transcription/Translation System which contains T7 polymerase and rabbit reticulocyte lysate. For the *in vitro* binding assays, I individually incubated GST-tagged protein or GST-alone bound to resin with ^{35}S-Methionine-labelled protein in binding buffer and at room temperature (section 2.8.1). After allowing a period for binding, I washed the resin samples multiple times and subjected them to SDS-PAGE, transferred the separated proteins to nitrocellulose membrane and exposed them at -80°C using enhancer film. The signal detected on the autoradiogram shows if and to a certain extent how well the ^{35}S-Methionine-labelled protein binds to the protein on resin.

I first analysed whether GST-Dragon immobilised on resin would bind ^{35}S-Methionine-labelled Sas6 protein directly (Figure 5-5A) and secondly, if GST-Sas6 immobilised on resin would bind ^{35}S-Methionine-labelled Dragon protein directly (Figure 5-5B). As a negative control, I used GST-alone bound to resin. ^{35}S-Methionine-labelled Sas6 does not bind to GST alone (lane 2) but shows a strong binding with GST-Dragon. In the reciprocal

experimental set up of the *in vitro* binding assays, GST-Sas6 bound to ^{35}S-Methionine-labelled Dragon whereas GST-alone did not (Figure 5-5B).

In summary, the *in* vitro transcription-translation system and binding assay, which contains only the two proteins of interest confirms that Dragon and Sas6 protein bind each other directly *in vitro*, accounting for the co-purification of Sas6 and Dragon in complex from cultured *Drosophila* cells and *Drosophila* syncytial embryos.

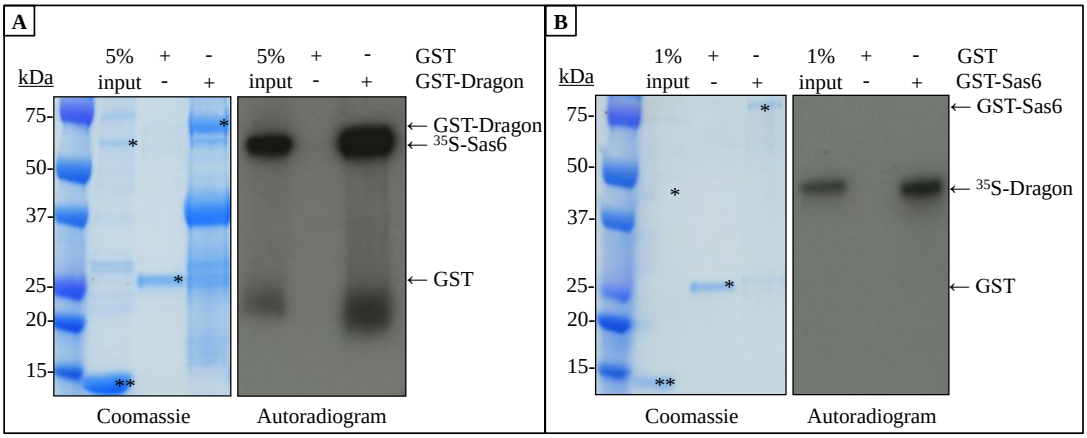

Figure 5-5 Sas6 and Dragon interact directly *in vitro*. (A) GST-Dragon was incubated with ^{35}S-Methionine-labelled Sas6 and (B) GST-Sas6 was incubated with ^{35}S-Methionine-labelled Dragon. The complexes were subjected to SDS-PAGE and autoradiography. Both interaction assays confirm that Sas6 and Dragon interact directly with each other *in vitro*. GST (negative control) did not exhibit any interaction with ^{35}S-Methionine-labelled Dragon nor ^{35}S-Methionine-labelled Sas6. * indicates protein sample loaded; ** indicates reticulocyte lysate residue.

5.2.4.2 The C-terminal region of Sas6 binds directly to Dragon *in vitro*

After I identified full-length Dragon and Sas6 as directly interacting proteins *in vitro*, I wanted to further understand which regions of the proteins were required for the direct protein-protein interaction.

To analyse which region within Sas6 interacts with Dragon *in vitro*, I generated vectors containing fragments of Sas6 downstream of a T7 promotor, to generate protein fragments of Sas6 with the Promega TnT® T7 Quick Coupled Transcription/Translation System for radioactive labelling. I then performed binding assays with these ^{35}S-Methionine-labelled Sas6 fragments and GST-Dragon (full-length) bound to resin (section 2.8.1). The Sas6 fragments I tested in this way are summarised in Figure 5-6 and Figure 5-7.

The first series of Sas6 fragments were designed according to the predicted secondary structure of Sas6 (Figure 5-9). These Sas6 fragments represented the N-terminal head-domain of Sas6 (N, aa1-180); the majority of the coiled-coil domain (CC, aa181-408); the N-terminal head- and majority of the coiled-coil domain together (NC, aa1-408); and the coiled-coiled domain with the unstructured most C-terminal part (CC+C, aa181-472). I carried out binding assays with each of these ^{35}S-Methionine-labelled Sas6 fragments and GST-Dragon before carrying out SDS-PAGE and protein transfer onto nitrocellulose membrane for autoradiography. I observed direct interaction of Dragon only with the Sas6 fragment containing the coiled-coiled and unstructured C-terminal region (CC+C, aa181-472). None of the other analysed Sas6 fragments interacted with Dragon (Figure 5-6, Figure 5-7A).

We know from structural studies that the N-terminal head domain of Sas6 forms the ‘inner hub’ of the centriole cartwheel and that the N-terminal part of the coiled-coiled domain of Sas6 molecules dimerise and form the cartwheel spokes of the centrioles (Figure 1-8, Figure 1-7). My above described analysis suggests that a region at the C-terminal part of the Sas6 coiled-coil domain and adjacent upstream sequence is important for interaction with Dragon. The coiled-coil region alone (CC) and the N-terminus are not sufficient for binding to Dragon. This suggests an interaction of Dragon with Sas6 in its so far uncharacterised C-terminal coiled-coil region.

To further narrow down the region of Sas6 necessary for binding Dragon, I generated additional Sas6 fragments from within the fragment aa181-472. These constructs are stepwise truncations from the N- or C-terminus of the Sas6 aa181-472 fragment (Figure 5-6). Each of these Sas6 fragments was labelled with ^{35}S-Methionine by coupled transcription-translation reaction and tested for its ability to bind GST-Dragon immobilised on resin. The

most C-terminal truncated Sas6 construct analysed that still exhibits direct binding with Dragon is the Sas6 fragment aa1-462 (Figure 5-6, Figure 5-7C). Sas6 fragments smaller, including aa1-452, do not bind Dragon. Hence, the very C-terminal 10aa of Sas6, which represent the unstructured C-terminus of the protein according to secondary structure prediction in Figure 5-9, are not essential for binding with Dragon. Removal of N-terminal sequence from Sas6 did not prevent interaction with Dragon until residue 351 (construct aa351-472; Figure 5-6, Figure 5-7B).

Taken together, Sas6 protein fragments aa1-462 and aa351-472 are respectively the most C- and N-terminal truncated protein fragments which are still able to directly interact with Dragon *in vitro*. Thus the Sas6 protein region 351-462aa is necessary for interaction with Dragon. Interestingly, this region of Sas6 shows conservation between species (Figure 5-8).

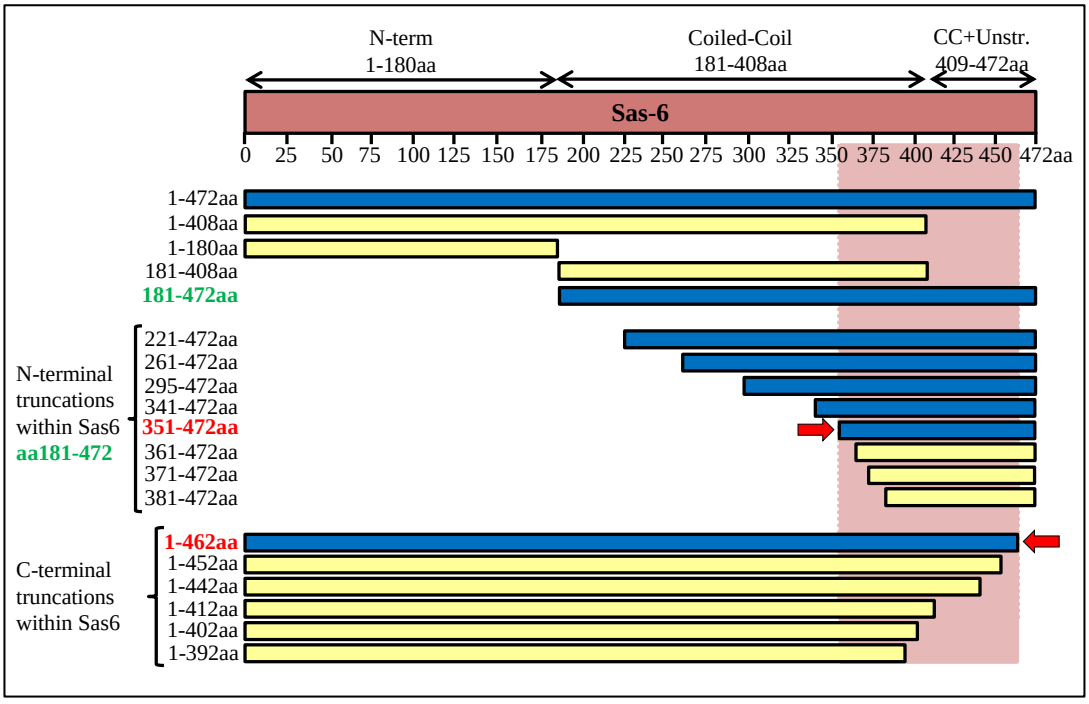

Figure 5-6 Schematic diagram of interactions of Sas6 protein fragments with Dragon *in vitro*. Sas6 fragments are shown relative to secondary structure features of Sas6 (N-term, coiled-coil, C-terminal coiled-coil and unstructured region). 19 Sas6 fragments were analysed corresponding to the indicated numbers of amino acids. Blue, Sas6 fragments that interact with Dragon *in vitro*. Yellow, Sas6 fragments that do not interact with Dragon *in vitro*. Units of the interacting region are identified by red arrows and pink shading.

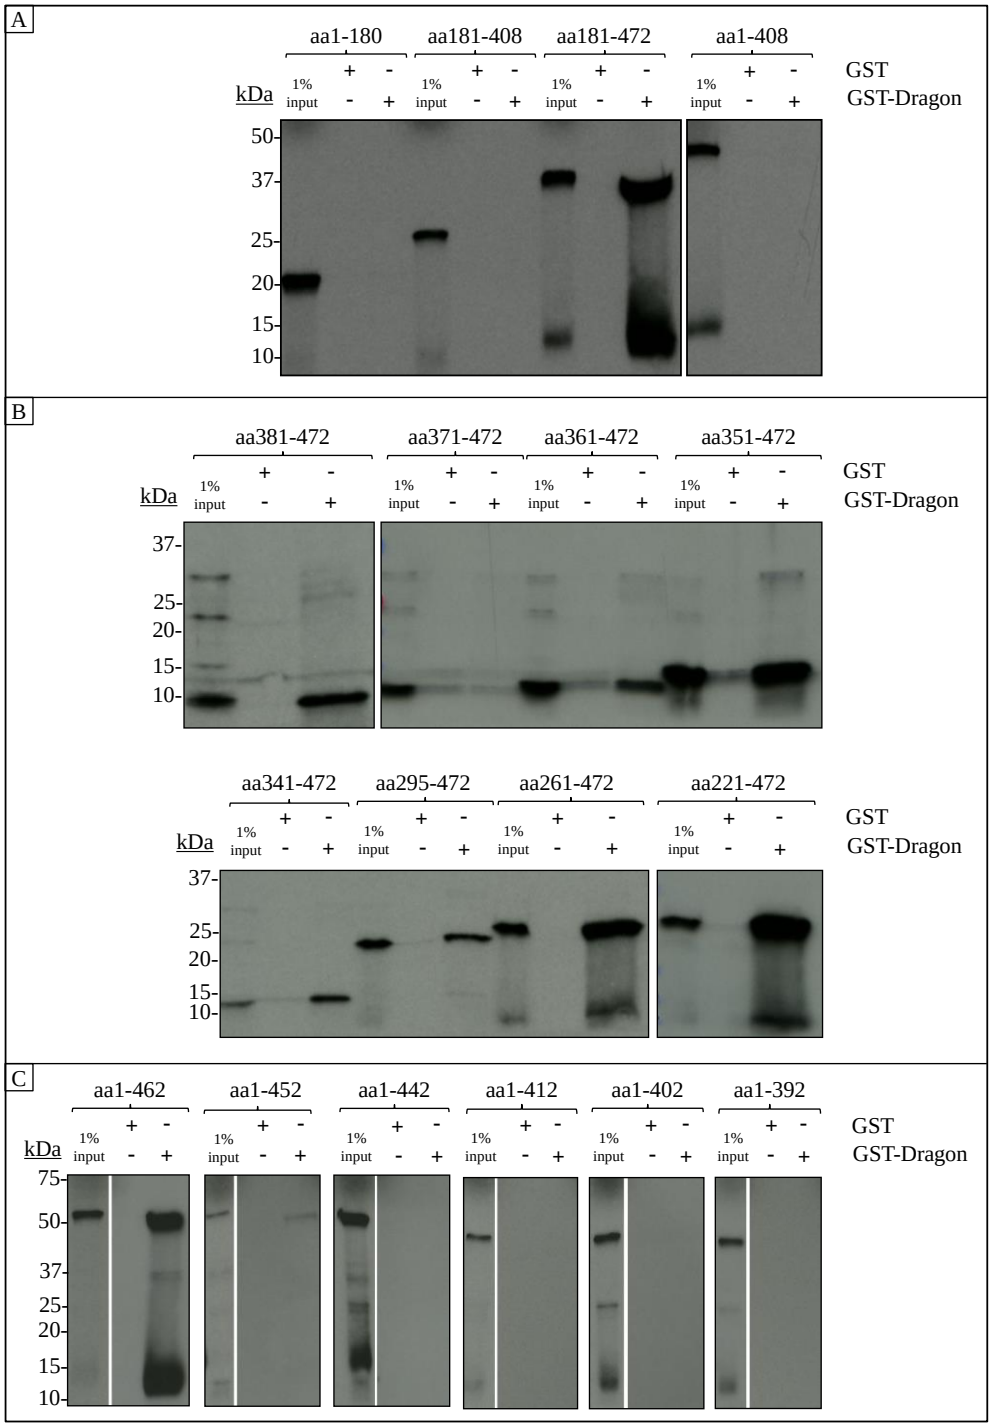

Figure 5-7 Autoradiograms of Sas6 fragments and their interaction with full-length Dragon. (A) Sas6 segment aa181-472 interacts with Dragon. (B) Testing for the smallest Sas6 fragment with stepwise N-terminal truncations within aa181-472 that interacts with Dragon reveals aa351-472. (C) Testing for the most C-terminal truncation within Sas6 that allows for interaction with Dragon reveals aa1-462. Complementary to Figure 5-6. Shown is 1% input of ^{35}S-Methionine-labelled Sas6 constructs and their interaction with GST (negative control) or GST-Dragon. Autoradiograms in (C) were cropped from the same exposure, original film in Appendix D.

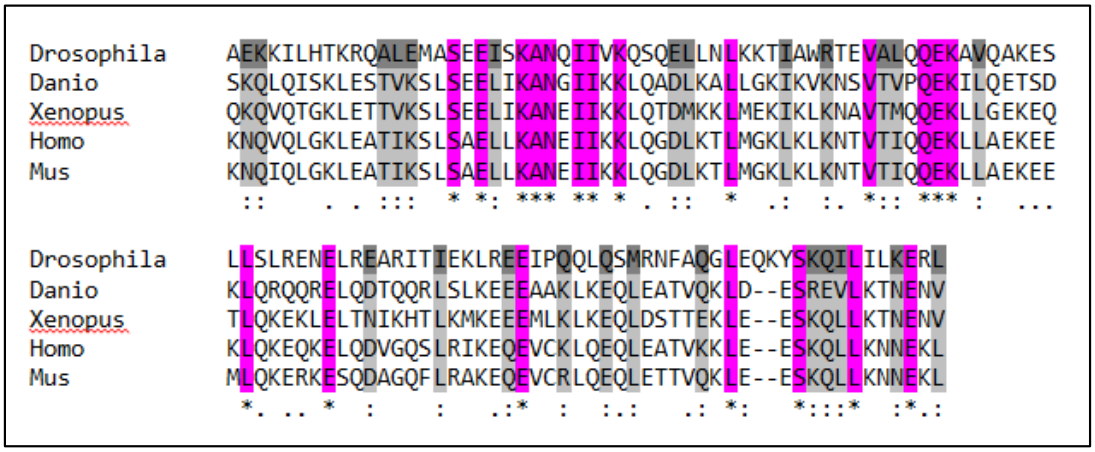

Figure 5-8 Alignment of the Dragon interacting region of *Drosophila melanogaster* Sas6 (aa351-462) shows that it is highly conserved. The five aligned species are: *Drosophila melanogaster*, *Danio rerio*, *Xenopus laevis*, *Homo sapiens* and *Mus musculus*. Pink background highlights amino acids conserved between species; grey background highlights similar amino acid groups between species, with dark grey background highlighting the amino acid for *Drosophila melanogaster*. Alignment generated with Clustal Omega [284].

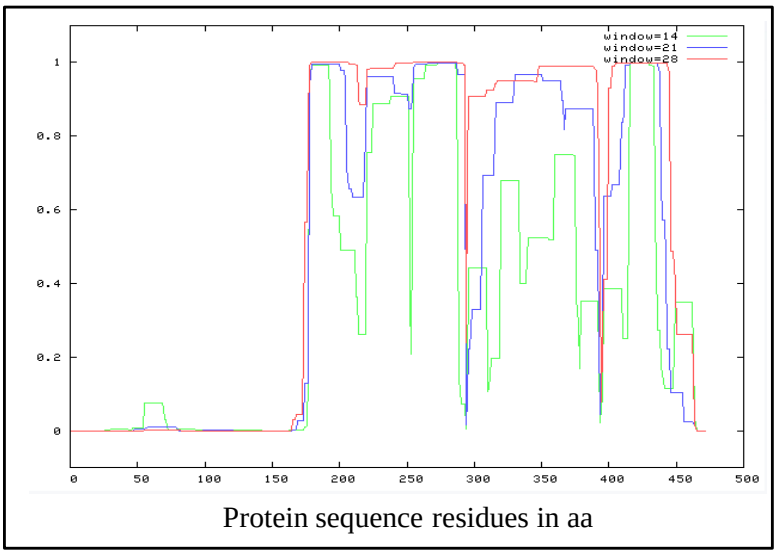

Figure 5-9 Secondary structure prediction shows that Dragon-interacting domain of Sas6 (aa351-462) is the C-terminal part of a predicted coiled-coil domain. Sas6 full-length secondary structure prediction shows the N-terminal head domain between residues 1 and 180, followed by a predicted coiled-coil domain and a small C-terminal unstructured region. Windows described in [286]; the higher the window number, the better is the distinction between coiled-coil and other regions. Analysing software: coils server [286].

5.2.4.3 The C-terminal coiled-coiled region of Dragon interacts directly with Sas6 *in vitro*

After I identified the Sas6 region aa351-462 within its coiled-coiled domain to interact directly with Dragon *in vitro*, I wanted to determine which part of Dragon binds directly to Sas6. To this end I constructed recombinant DNAs containing a T7 promotor and fragments of the Dragon DNA sequence, which I used to generate ^{35}S-Methionine-labelled Dragon protein fragments by coupled transcription-translation. I divided the Dragon protein fragments into N- and C-terminal parts (aa1-171 and aa172-339 respectively), and approximate thirds (aa1-113, aa114-243 and aa244-339 respectively) (Figure 5-10). I then performed binding assays with these ^{35}S-Methionine-labelled Dragon protein fragments and GST-Sas6 immobilised on resin (section 2.8.1). The fragments aa1-113, aa1-171 and aa114-243 did not interact with Sas6 whereas the fragment aa172-339 bound efficiently. The smaller C-terminal Dragon fragment, aa244-339, interacted with Sas6 but more weakly. I then expressed a Dragon fragment, aa191-318, designed to cover the predicted C-terminal coiled-coil domain of the protein (Figure 5-12). This fragment of Dragon (aa191-318) interacted with Sas6 as efficiently as full-length Dragon (Figure 5-11). This coiled-coil region of Dragon exhibits a high homology with *Danio rerio*, *Mus musculus* and *Homo sapiens*, *Xenopus (Silurana) tropicalis* and *Chrysemys picta bellii* (Figure 5-13).

In summary, the *in vitro* binding assays identified aa191-318 of Dragon as the binding domain for Sas6 protein, which corresponds to a predicted and conserved coiled-coil domain. I also showed that the aa351-462 segment of Sas6 interacts directly with Dragon (Figure 5-14).

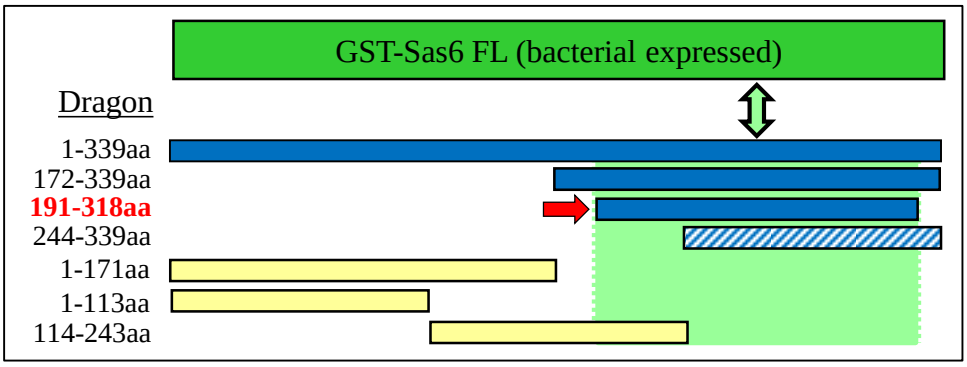

Figure 5-10 Schematic image of Dragon protein fragments that were tested for direct interaction with full-length Sas6 *in vitro*. The binding assays identified the C-terminal Dragon aa191-318 domain as the smallest fragment to strongly interact with Sas6. Blue, interaction; blue stripes, weak interaction; yellow, no interaction of Dragon fragment and Sas6 *in vitro*.

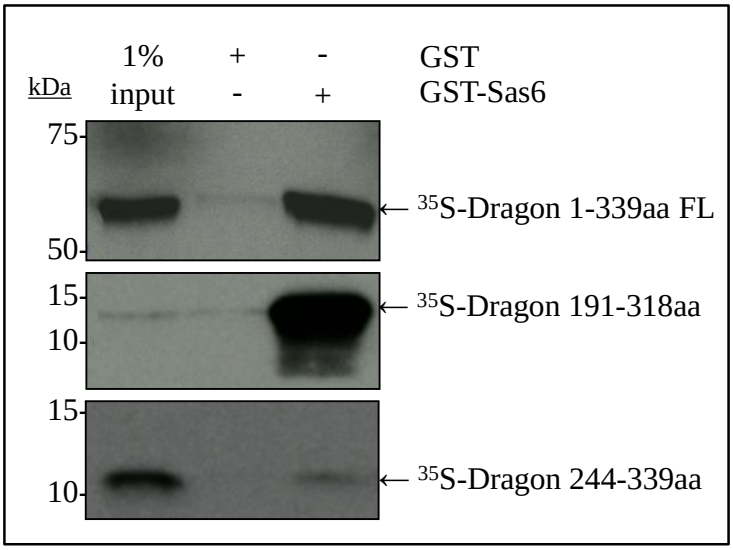

Figure 5-11 Autoradiograms showing binding of Sas6 with Dragon full-length and Dragon aa191-318. In contrast the comparably weak interaction with the smaller Dragon aa244-339 fragment. GST and GST-Sas6 immobilised on resin were incubated with ^{35}S-Methionine-labelled Dragon full length (aa1-339), aa191-318 or aa244-339. 1% input of the ^{35}S-Methionine-labelled Dragon constructs and the resin complexes were then subjected to SDS-PAGE and autoradiography. Complementary to Figure 5-10.

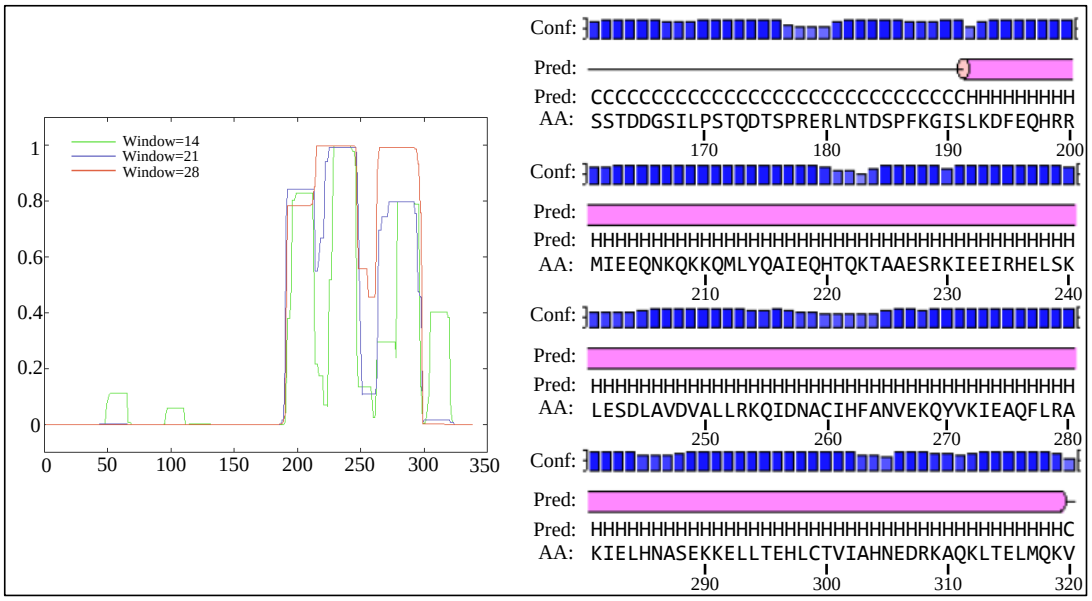

Figure 5-12 Secondary structure prediction of Dragon aa191-318, identified as interacting directly with Sas6 *in vitro*. This region of Dragon is predicted to be the main coiled-coil structure (right, pink) within the protein. Analysing software: coils server (left) [286] and Psipred (right) [285].

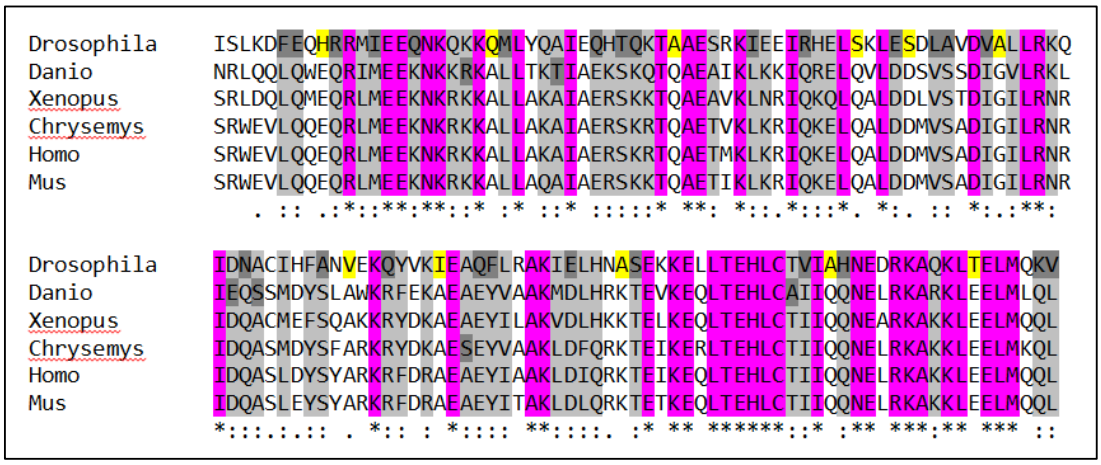

Figure 5-13 Alignment of *Drosophila melanogaster* Dragon aa190-320 with other species reveals conservation of the coiled-coil domain. The five aligned species are: *Drosophila melanogaster*, *Danio rerio*, *Xenopus laevis*, *Chrysemys picta bellii*, *Homo sapiens* and *Mus musculus*. Pink, amino acids conserved between all analysed species; grey, similar amino acid groups between species; dark grey, the single divergent amino acid within the analysed species; and yellow, a single divergent amino acid in *Drosophila* compared to all other analysed species. Alignment generated with Clustal Omega [284].

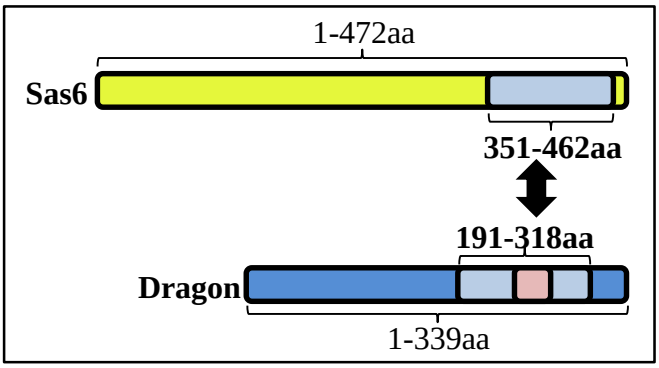

Figure 5-14 Summary figure of *in vitro* direct interaction assays. The C-terminal Sas6 aa351-462 (light blue) interacts directly with C-terminal Dragon aa191-318 (light blue) *in vitro*. Pink, Dragon interaction motif aa260-286 (as described in section 5.2.5).

5.2.4.4 Dragon interacts with itself *in vitro*

Sas6 molecules are known to dimerise via their coiled-coil regions and assemble into 9-fold cartwheel structures via their N-terminal head domains. This led me to consider whether Dragon, like Sas6, might oligomerise. I applied the *in vitro* direct binding assay used in previous sections to answer this question. I incubated full-length GST-Dragon bound to resin with full-length ^{35}S-Methionine-labelled Dragon in a binding assay, washed the resin to remove any unbound ^{35}S-Methionine-labelled Dragon, and subjected aliquots to SDS-PAGE and transferred the separated proteins onto nitrocellulose membrane for autoradiography. This showed that full-length Dragon molecules interact directly with each other. To characterise which region of Dragon enables oligomerisation, I carried out binding assays with the previously described ^{35}S-Methionine-labelled Dragon fragments and GST-Dragon (full-length) and GST-alone control (Figure 5-15). This revealed the C-terminal third of Dragon (aa244-339) as the smallest analysed Dragon fragment which can efficiently bind full-length Dragon directly (Figure 5-16). This region overlaps with the region that interacts with Sas6 (aa191-318; section 5.2.4.3). Significantly, the aa244-339 segment of Dragon was not able to bind Sas6 protein as efficient as aa191-318 (section 5.2.4.3). The analysis of the

smallest protein region necessary for oligomerisation of Dragon still needs to be analysed further.

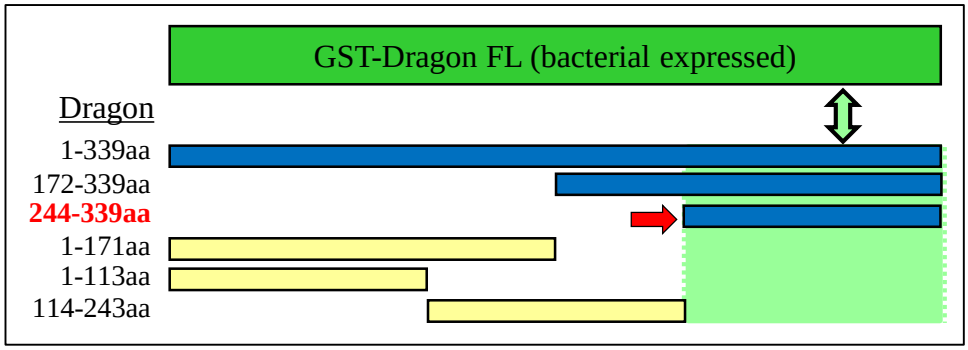

Figure 5-15 *In vitro* interaction analysis shows that Dragon interacts with itself at its C-terminus. Five Dragon fragments representing thirds and halves of the protein show that Dragon C-terminus is important for potential oligomerisation, with the most narrow analysed fragment covering aa244-339.

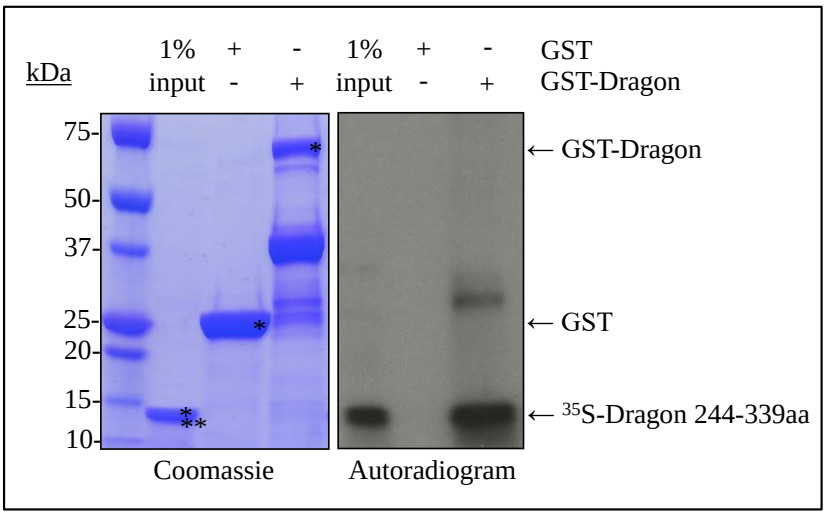

Figure 5-16 Dragon C-terminus (aa244-339) interacts with Dragon full-length *in vitro*. Protein coomassie gel and autoradiography show that ^{35}S-Methionine-labelled Dragon aa244-339 directly interacts with Dragon full-length protein. * protein sample loaded; ** reticulocyte lysate residue.

5.2.5 Identification of the interaction motif (IM) in Dragons' C-terminal binding domain which is essential for interaction with Sas6

5.2.5.1 *In vitro* direct interaction screen of Dragon mutants, to identify a Dragon interaction motif necessary for the binding of Sas6

In section 5.2.4.3, I described a region of 128aa within the C-terminus of Dragon aa191-318 as able to bind Sas6. To narrow down the binding region I made small deletions within the conserved binding domain (Dragon aa191-318) by site-directed mutagenesis of grouped conserved amino acids. These mutants are summarised in Figure 5-17. These mutant constructs were used to generate ^{35}S-Methionine-labelled proteins *in vitro* that were used in binding assays with GST-Sas6. The outcome of these experiments is summarised in Figure 5-17. It can be seen that the smallest deletion which abolishes Dragon's binding to Sas6 is aa260-286. Interestingly, three independent and smaller deletions within the region of Dragon (aa260-266, aa267-281 and aa282-286) are still able to bind Sas6 (Figure 5-18). Two further but larger deletion mutants, which include the 260-286aa deletion, also abolish binding of Sas6, namely deletions aa220-286 and aa220-318. This confirms the importance of aa260-286 of Dragon, in its interaction with Sas6. All other tested Dragon-mutants that carry a deletion outside of aa260-286 bind Sas6 efficiently *in vitro*.

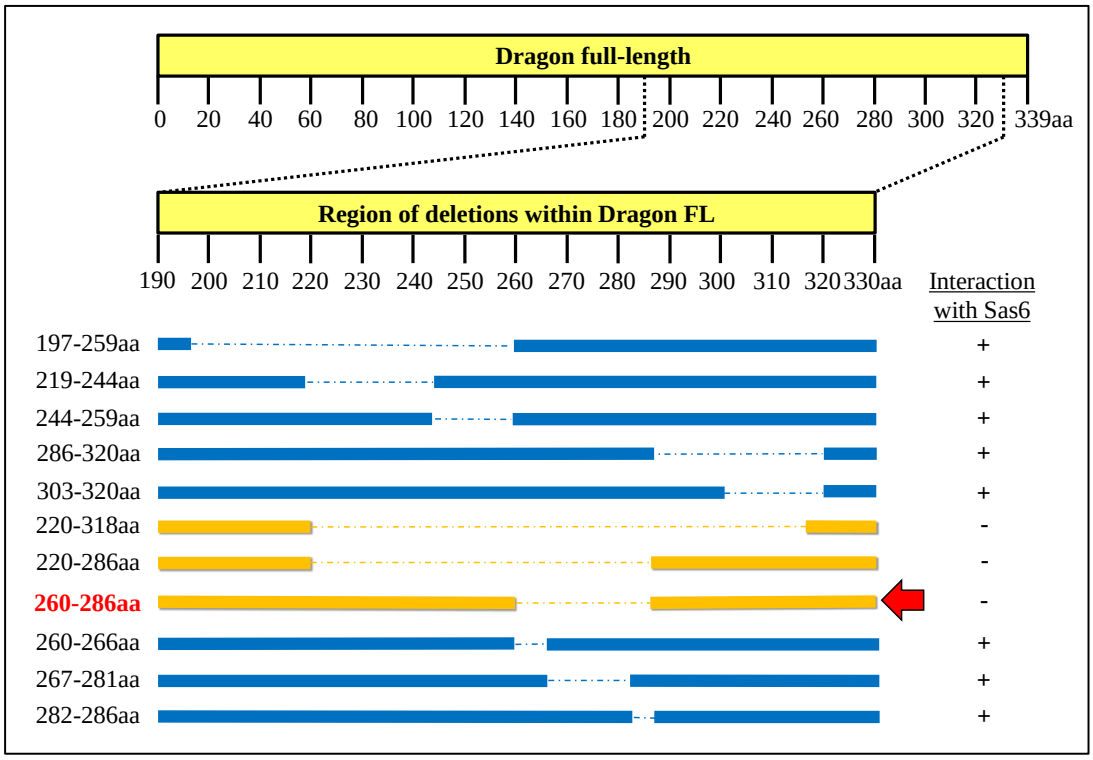

Figure 5-17 Dragon deletion mutants used to identify interaction motif (IM) for binding to Sas6 as aa260-286. 11 Dragon mutants were generated in full-length Dragon protein by site-directed mutagenesis, with deletions indicated. ^{35}S-Methionine-labelled mutant proteins were used in direct *in vitro* interaction assays with Sas6. +, *in vitro* interaction of Sas6 with Dragon mutant. -, no *in vitro* interaction of Sas6 with Dragon mutant.

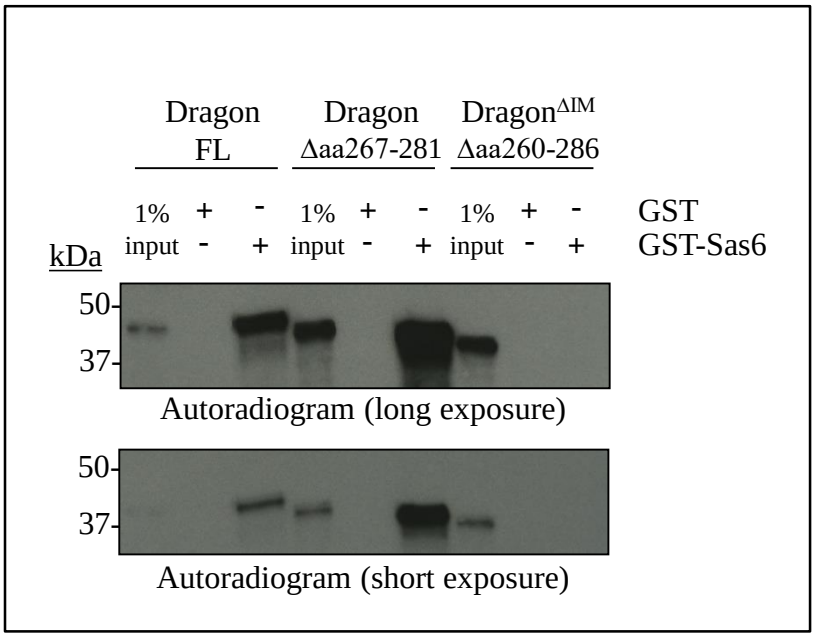

Figure 5-18 The mutant Dragon$^{\Delta IM}$ (DragonΔaa260-286) is unable to interact with Sas6 *in vitro*. Autoradiography of Sas6 interaction with ^{35}S-Methionine-labelled Dragon FL, DragonΔaa267-281 and Dragon$^{\Delta IM}$ (Δaa260-286); confirming interaction of the full-length proteins Sas6 and Dragon but that deletion of aa260-286 within Dragon abolishes this interaction. A smaller deletion in DragonΔaa267-281 still allows for interaction with Sas6. Short and long exposures confirm the lost direct interaction between Dragon$^{\Delta IM}$ and Sas6.

5.2.5.2 Purification of GFP-Dragon constructs from *Drosophila* cell culture, transiently transfected with Sas6 and Dragon variants, confirms that the Dragon-IM region is essential for interaction with Sas6 *in vivo*

Having identified a Dragon deletion (Δaa260-286) that fails to bind Sas6, I wished to determine the consequences of expressing this protein *in vivo*. Therefore, I transiently transfected *Drosophila* cell culture with myc-Sas6 and GFP; myc-Sas6 and GFP-Dragon; and myc-Sas6 and GFP-Dragon$^{\Delta IM}$ and performed GFP-purifications with extracts of each of the three transiently transfected cell culture samples. I then determined by Western Blotting and antibody staining, which Dragon construct could interact with Sas6 (Figure 5-19). I used antibodies against GFP, myc and α-tubulin to detect GFP/GFP-Dragon/GFP-Dragon$^{\Delta IM}$, myc-

Sas6 and α-tubulin (control) respectively. Figure 5-19 shows the according Western Blots of the GFP-purifications and inputs/cell lysates. The inputs confirm that each combination of transient transfection was efficient, as anti-GFP detects GFP, GFP-Dragon and GFP-Dragon$^{\Delta IM}$, anti-myc detects myc-Sas6, and α-tubulin is detected in all three samples. The Western Blots of the GFP-purifications confirm that GFP, GFP-Dragon and GFP-Dragon$^{\Delta IM}$ are present in the respective cell samples. Significantly, I could only detect myc-Sas6 associated with GFP-Dragon. I could not detect myc-Sas6 with GFP only or with GFP-Dragon$^{\Delta IM}$. Thus the deletion of aa260-286 in otherwise full-length Dragon abolishes the interaction with Sas6 *in vivo*, confirming my *in vitro* findings.

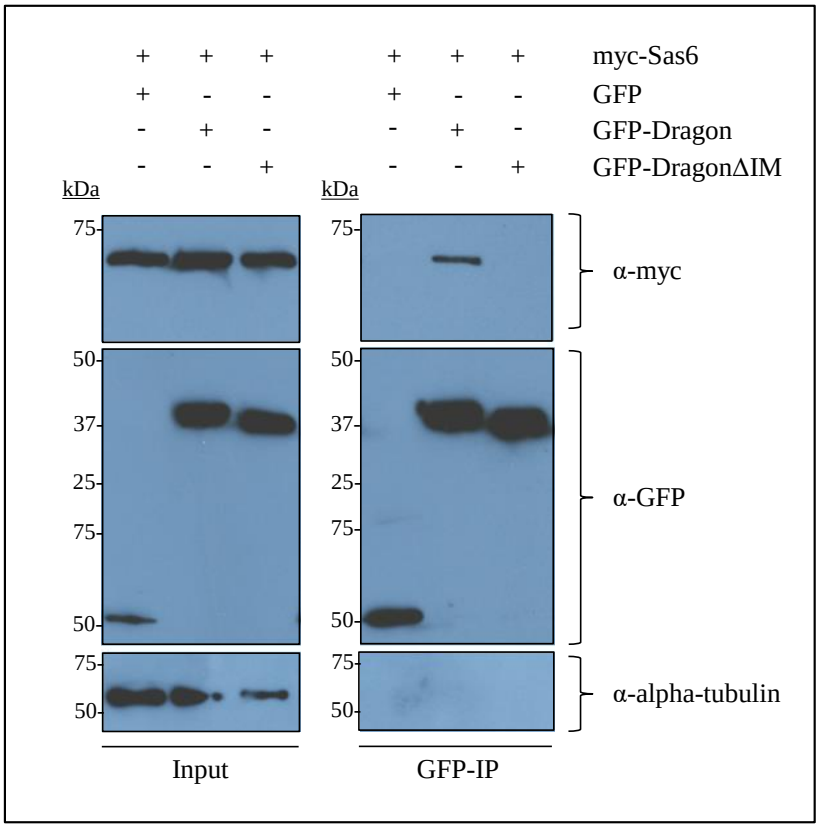

Figure 5-19 Co-IP confirms *in vivo* that Dragon$^{\Delta IM}$ cannot interact with Sas6. *Drosophila* cell cultures were transiently transfected with myc-Sas6 and GFP-Dragon$^{\Delta IM}$, GFP-Dragon or GFP, followed by GFP-IP. Western Blot and anti-myc staining shows loss of interaction between Sas6 and GFP-Dragon$^{\Delta IM}$, whereas interaction occurs between Sas6 and Dragon. Anti-GFP stains for GFP, GFP-Dragon and GFP-Dragon$^{\Delta IM}$. Anti-α-tubulin control and anti-myc signals detected in the input samples.

5.2.5.3 GFP-Dragon$^{\Delta IM}$ and its effect on centrosome numbers compared to GFP-Dragon and *Drosophila* WT cells

I then wished to determine whether the Dragon$^{\Delta IM}$ mutant could rescue loss of centriole depletion resulting from Dragon depletion (section 5.2.3.1). This experiment necessitated that I deplete Dragon efficiently with dsRNA against its UTR sequence so that I could utilise the mutant gene that does not carry the UTR sequences. To determine whether UTR mediated RNAi had similar effect on centriole duplication as observed with RNAi using Dragon CDS I carried out three 4 day rounds of RNAi directed against GST (control), Dragon CDS and Dragon UTRs (Figure 5-20). The loss of centrosomes was significant in a comparison between GST (control) and both Dragon depletions (CDS and UTRs). There is also a significant difference in cells without centrosomes when RNAi against Dragon CDS is compared to Dragon UTRs. But this difference is less significant compared to the GST control. Thus, depletion of Dragon by dsRNA CDS and UTRs are efficient and have a significant effect on centriole duplication, causing loss of centrosomes.

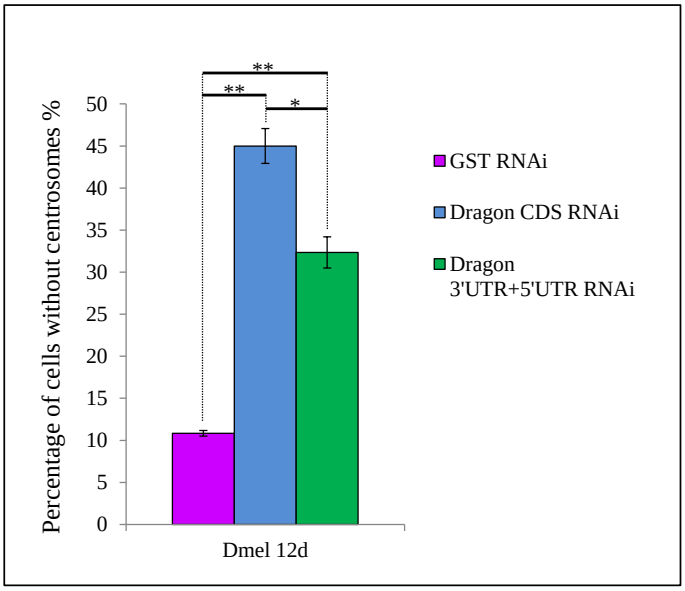

Figure 5-20 Depletion of Dragon using dsRNA against Dragon CDS or Dragon UTRs both lead to loss of centrosomes. *Drosophila* cell culture was depleted of Dragon by RNAi (dsRNA CDS or dsRNA UTRs) versus GST control RNAi. Centrosome numbers were scored on day 12, after three rounds of depletion. Error bars represent standard error; 3x200 cells counted; significance was calculated by t-test.

Having identified conditions for efficient depletion of Dragon by RNAi directed against its UTRs, I generated a cell line stably expressing GFP-Dragon$^{\Delta IM}$ from the constitutively active promotor poly-Ubiquitin. RNAi directed against Dragon UTR in control cells resulted in an increase of cells lacking centrosomes, from 13.3% to 26.7%. A similar result was seen for GFP-Dragon$^{\Delta IM}$ expressing cells where cells without centrosomes increase from 6.8% to 15.2%. But GFP-Dragon expressing cells show only a slight increase of cells without centrosomes, from 14.8% to 21.2%. The ratio of cells without centrosomes after GST RNAi versus Dragon UTRs RNAi is 1:2 in control cells, 1:2.2 in GFP-Dragon$^{\Delta IM}$ expressing cells, and 1:1.4 in cells expressing GFP-Dragon. Hence, Dragon$^{\Delta IM}$ fails to rescue the depletion of endogenous Dragon (Figure 5-21). The Western Blot in Figure 5-22 shows the complete depletion of endogenous Dragon after RNAi of Dragon UTRs and the expression of constitutively expressed GFP-Dragon and GFP-Dragon$^{\Delta IM}$.

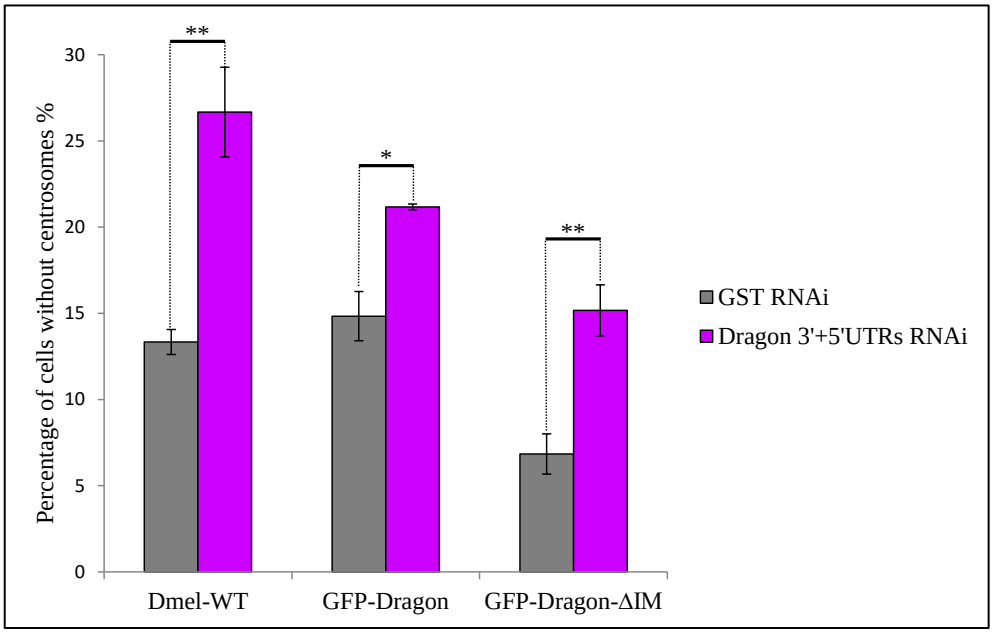

Figure 5-21 Expression of GFP-Dragon$^{\Delta IM}$ fails to rescue loss of centrosomes resulting from Dragon depletion. Cultured *Drosophila* cells stably expressing GFP-Dragon or GFP-Dragon$^{\Delta IM}$ were depleted of endogenous Dragon by dsRNA *Dragon UTRs* over two rounds of RNAi for eight days. Centrosome numbers were analysed after staining with the centrosomal marker D-Plp. *Drosophila* wild-type cells and GFP-Dragon$^{\Delta IM}$ expressing cells fail to rescue loss of centrosomes after depletion of endogenous Dragon. Cells expressing GFP-Dragon reveal a milder effect on loss of centrosomes. Error bars represent standard error; 3x200 cells counted; significance was calculated by t-test.

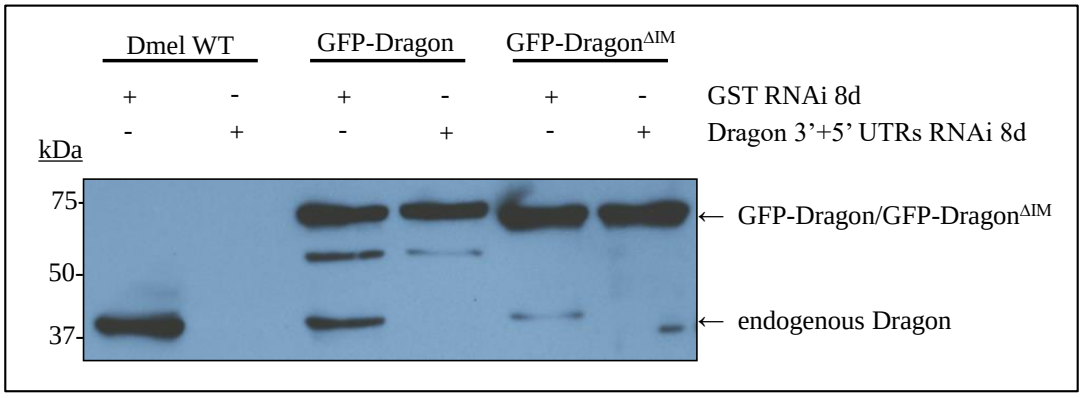

Figure 5-22 Endogenous Dragon is fully depleted from wild-type *Drosophila* cells and cells stably expressing GFP-Dragon or GFP-Dragon$^{\Delta IM}$ after two rounds of RNAi against Dragon UTRs over 8 days. Constitutively expressed GFP-Dragon and GFP-Dragon$^{\Delta IM}$, and endogenous Dragon are revealed by anti-DragonN antibody staining after Western Blot.

5.2.6 Study of the human homologues GoRab and HsSas6, in relation to the findings for *Drosophila* Dragon and Sas6

5.2.6.1 The human homologues GoRab and HsSas6 interact directly *in vitro*

As human cells have homologues for both proteins Dragon and Sas6, namely GoRab and HsSas6 respectively, I wished to analyse if these human homologues also interacted directly. The human homologue GoRab has two functional isoforms, variant 1 and variant 3. The first isoform represents the full-length protein (395aa) and the latter is a shorter version (247aa), which lacks the C-terminal extension of variant 1. When comparing these two variants with *Drosophila* Dragon by homology, it is evident, that only GoRab variant 1 contains the region homologous to *Drosophila* Dragon-IM (aa260-286) and the full *Drosophila* Sas6-binding domain (aa191-318). GoRab variant 3 contains only aa191-247, which corresponds to the N-terminal region of the *Drosophila* Dragon for Sas6 binding (aa191-246) upstream of *Drosophila* Dragon-IM (aa260-286) (Figure 5-23, Figure 5-24). To

study if human GoRab and HsSas6 interact directly with each other, I expressed GST-HsSas6 in *E. coli* and bound it to Glutathione Sepharose 4B resin via the GST tag (section 2.5.1). I generated ^{35}S-Methionine-labelled GoRab variant 1 and variant 3 by coupled *in vitro* transcription-translation reaction. I then performed *in vitro* binding assays (section 2.8.3) with GST-HsSas6 and ^{35}S-Methionine-labelled GoRab variant 1 or variant 3, subjected the proteins to SDS-page and transferred the separated proteins onto nitrocellulose membrane for autoradiography. The autoradiograms show that GoRab variant 1 directly interacts with HsSas6 but not the negative control GST-alone (Figure 5-25A). In contrast, ^{35}S-Methionine-labelled GoRab variant 3 interacts similarly with the negative control GST and GST-HsSas6, indicative of background binding and not due to the interaction of ^{35}S-Methionine-labelled GoRab variant 3 with HsSas6.

In summary the human counterparts of Dragon and Sas6, GoRab variant 1 and HsSas6, also interact directly with each other *in vitro*. A second isoform of the human homologue, GoRab variant 3, which is a shorter C-terminal truncated isoform of variant 1, does not interact directly with HsSas6 *in vitro*.

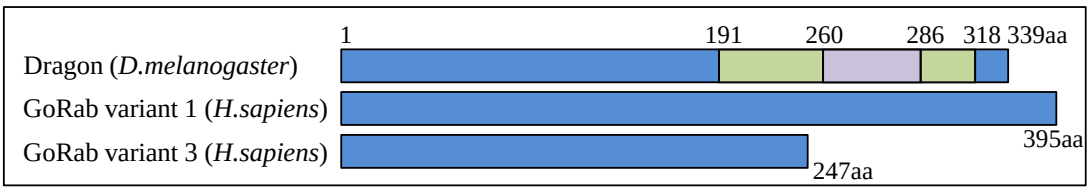

Figure 5-23 Homology between *Drosophila* Dragon and *Homo sapiens* GoRab variant 1 and variant 3. *Drosophila* Dragon aa191-318 (green) is the Sas6 binding domain identified by direct *in vitro* binding assays, and aa260-286 (purple) is the Dragon-IM that is necessary for Sas6 to bind Dragon. GoRab variant 1 includes the full and according homologous region of Dragon aa190-318, whereas GoRab variant 3 is a shorter isoform which only contains the most N-terminal homologous region and lacks the homologous Dragon-IM and the upstream sequence.

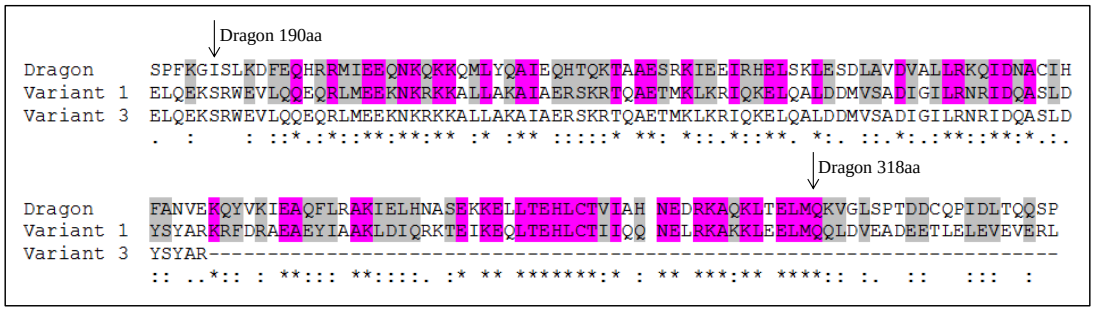

Figure 5-24 Alignment of *Drosophila* Dragon aa185-338 and *Homo sapiens* GoRab variant 1 and variant 3. GoRab variant 1 and variant 3 share the same sequence of amino acids but differ in length. Highlighted are the same amino acids that are identical between Dragon and GoRab (pink) or similar (grey). Alignment generated with Clustal Omega [284].

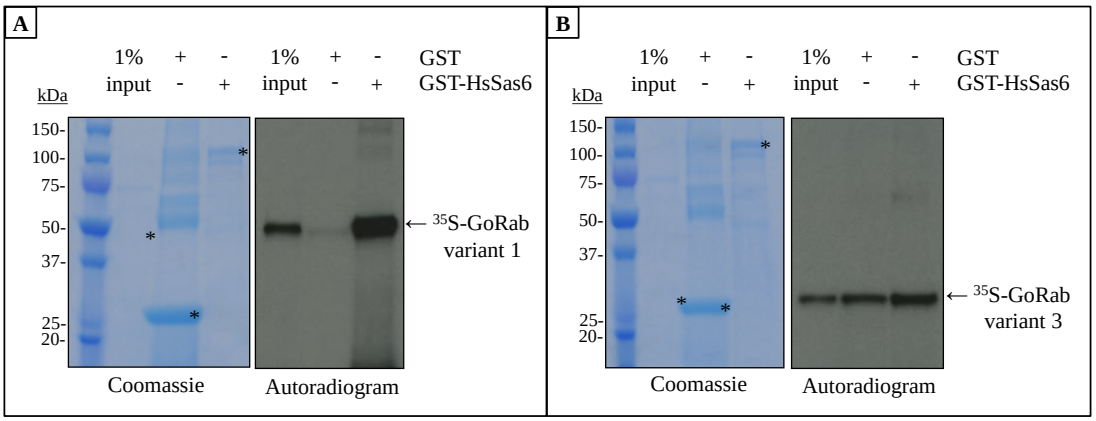

Figure 5-25 Only the long isoform of GoRab variant 1 directly interacts with HsSas6 *in vitro*, confirming findings for *Drosophila* Dragon and Sas6. ^{35}S-Methionine-labelled GoRab variant 1 and variant 3 were individually assessed for binding to HsSas6 *in vitro*. Coomassie stainings show protein inputs for GST and GST-HsSas6. Autoradiograms show direct interaction of GoRab variant 1 with HsSas6 but lacks specific interaction for GoRab variant 3 with HsSas6.

5.2.6.2 Centrosome numbers are reduced in U2OS cells following GoRab RNAi

After I determined that HsSas6 and GoRab variant 1 could interact directly with each other *in vitro* (section 5.2.6.1), I wished to know whether depletion of GoRab in human cell culture

would reduce centrosome numbers, as observed after depletion of Dragon in *Drosophila* cell culture in section 5.2.3.1.

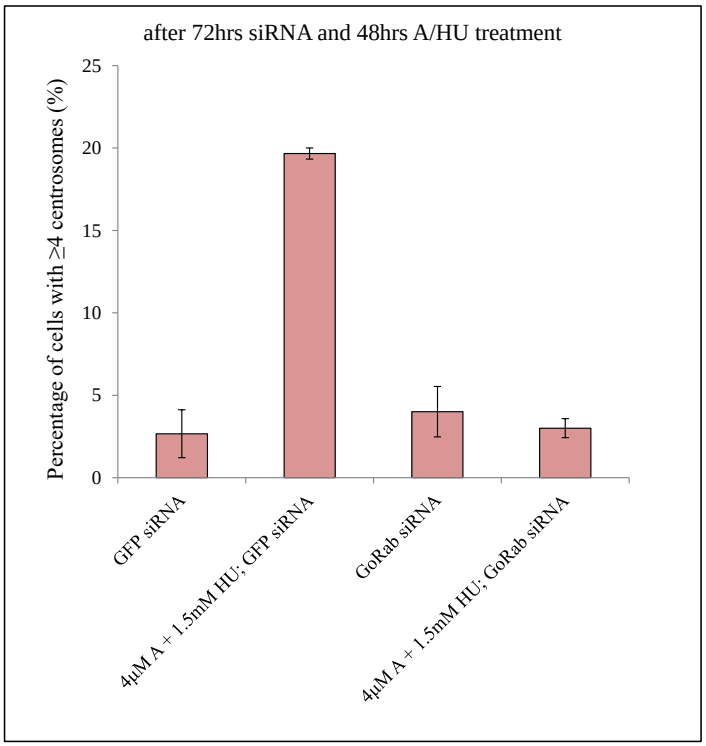

Figure 5-26 Depletion of GoRab in U2Os cells negatively affects centriole duplication. U2Os cells that are arrested in S-phase by Aphidicolin (A) and HydroxyUrea (HU) treatment and under control GFP siRNA conditions show a significant increase in cells with ≥4 centrosomes per cell. Treatment of U2Os cells with GoRab siRNA prevents an increase in cells with ≥4 centrosomes per cell, suggesting a negative effect on centriole duplication. Error bars represent standard error; 3x100 cells counted.

To address this question, I depleted GoRab via siRNA from U2OS cells and blocked the cells in S-phase 24 hours after transfection with Aphidicolin and Hydroxyurea before assessing centrosome numbers; GFP siRNA was used as a negative control (section 2.9.4). When U2OS cells are blocked in S-phase by Aphidicolin and Hydroxyurea, DNA duplication and therefore cell division is prohibited, but centriole duplication still occurs as normal leading to an increase in the number of centrosomes within each cell. Accordingly, cells treated with control RNAi and blocked in S-phase show an increase from 2.7% to 19.7% of

cells having ≥4 centrosomes per cell. By contrast, U2OS cells treated with GoRab siRNA alone exhibited just 4% of cells with ≥4 centrosomes per cell, which is comparable to the 3% of U2OS cells showing ≥4 centrosomes per cell after treatment with GoRab siRNA and being blocked in S-phase. This shows that duplication of centrosomes in S-phase blocked U2OS cells is prevented after depletion of GoRab. Thus, the homologues Dragon and GoRab appear to have roles in centriole duplication in *Drosophila* and human cells respectively.

5.3 Discussion

5.3.1 Dragon and the centrosome

It is curious why purification of Sas6 from cultured cells do not show other centriole duplication proteins. But most interestingly, the uncharacterised Dragon was present in all Sas6 purifications (Table 5-1). Indeed, Dragon and Sas6 appear to be in complex *in vivo*, when either is overexpressed in *Drosophila* cell cultures, or in *Drosophila* syncytial embryos overexpressing Dragon (Table 5-1 and Table 5-2). The levels/'number of peptides' of Dragon were increased when purified Sas6 is constitutively expressed in *Drosophila* syncytial embryos compared to induced overexpression of Sas6 in *Drosophila* cell culture. On the other hand treatment with okadaic acid to inhibit dephosphorylation by PP2A and treatment with MG132 to inhibit proteasomal degradation did not seem to affect the ratio of Sas6:Dragon. Thus, Dragon seems to associate with Sas6 in a phosphorylation independent manner. On the other hand, the constitutive expression of Dragon results in a higher number of Sas6 peptides in complex compared to the induced expression of Dragon, which can be due to constitutive versus induced expression. Alternatively, complex formation could be affected by the tag on the N- or C-terminus of Dragon. It is possible that the GFP-tag at the C-terminus interferes with the ability of Sas6 to be in complex with Dragon.

Dragon localises with Sas6 to the mother and procentriole/daughter centriole (Figure 5-2). Its presence at procentriole formation could indicate that it supports the process of daughter centriole formation [296]. An indication for a potential structural role of Dragon at the centriole is its localisation not only at the procentriole/daughter centriole but that it also remains co-localised with Sas6 at the mother centriole. Additionally, depletion of Dragon causes loss of centrosomes (Figure 5-4). To further understand the recruitment of Sas6 and Dragon to the centriole, additional structural illumination microscopy needs to be performed to study the interdependency of Dragon and Sas6 at the centriole when one or the other protein is depleted. This will shed light on their recruitment hierarchy to the site of procentriole

formation to determine whether this occurs sequentially, together, or interdependent, and the consequences of their depletion upon the centrosome structure.

5.3.2 Dragon and the Golgi

Dragon also localises to the Golgi (Figure 5-1), in accordance with previous observations with the human homologue GoRab [202]. Specifically it co-localises with Golgin-245 at the *trans*-Golgi (Figure 5-3), as was observed for the human homologue GoRab [202], and the GoRab interacting partner Rab6 [320]. Dragon's function at the *trans*-Golgi is not known but indications from mass spectrometry analyses of its complexes suggest a potential role in dependency to COPI. This is because five out of seven subunits of COPI were identified by mass spectrometry as co-purifying with Dragon from cultured *Drosophila* cells. Interestingly, COPI is one of three types of vesicles at the Golgi, in addition to COPII and clathrin-coated vesicles. These proteins are vesicle coat proteins with a diverse set of functions at the Golgi, representing division of the Golgi into three stages of maturation from the cisternal assembly stage to the carbohydrate synthesis stage and carrier formation (Figure 1-13) [321,322]. The three types of Golgi coat proteins function in direct protein and membrane trafficking, by selecting specific cargo proteins in different Golgi compartments. Proteins synthesized in the Endoplasmic Reticulum (ER) are selectively exported by COPII vesicles, which in turn then bud to form new *cis*-Golgi cisterna [323]. On the other hand, COPI vesicles function in the transfer of Golgi proteins between medial- and *trans*-Golgi cisternae, and additionally recycle proteins from the *cis*-Golgi to the ER [323–326]. The third vesicle type, clathrin-coated vesicles, are cargo carriers that form during cisterna disintegration at the *trans*-Golgi-network (TGN) and apparently recycle proteins from mature to newly formed TGN cisternae [327–329]. It is known that COPI protein forms two subcomplexes; the adaptor subcomplex made up of γ-β-δ-ζ-COPs and the cage-like subcomplex of α-β'-ε-COPs [330–334]. The mass spectrometry data shows that all subunits of the latter are present in the Dragon purifications from *Drosophila* cell culture (Table 5-3). Thus, suggesting a COPI specific function of Dragon at the Golgi.

That the subunits of COPI and COPII are not present in the Dragon complexes purified from *Drosophila* syncytial embryos most likely reflects the timing of the biosynthesis of the Golgi. The Golgi apparatus consists of small fragments in syncytial and gastrulating *Drosophila* embryos [335–338] but it mainly develops later to have small vesicles and tubules in early third-instar larvae (72 hours after fertilisation). Larger clusters of Golgi marked with GM130, p115, and Fringe appear in late third-instar larvae, and only at the pupa state do Golgi stacks appear (120 hours after fertilisation) [339,340]. Additional support for the hypothesis that *Drosophila* Dragon functions in the secretory pathway comes from the known interaction of the human homologue GoRab with Rab6 [202]. Rab6 functions in the recruitment of motor proteins and the retrograde transport from endosomes to the Golgi apparatus [341,342]. The absence of Rab proteins in complex with the purified Dragon from *Drosophila* cell culture is therefore surprising but may reflect the stability of this association. I was unable to reveal a function of Dragon at the Golgi because the attempted depletion of Dragon did not show any changes in the co-localisation with the *trans*-Golgi marker Golgin-245 or localisation of the *cis*-Golgi marker GM130 by fluorescent microscopy (data not shown, collaboration with Miss Chu). Several explanations are possible: either the RNAi was inefficient at depleting Dragon to a sufficient degree to see a Golgi phenotype; that the assay used was inadequate for deleting Dragon's Golgi function; or that indeed Dragon has no Golgi function. An interesting finding for more study is C-terminal binding protein (CtBP) that is present in complex with Dragon (Table 5-3). CtBP is required for the G2-mitotic checkpoint that leads to fission of the Golgi ribbon into separate Golgi stacks in mammalian cells [343], followed by further fragmentation and disassembly [344]. The specific function or the mechanism behind the disassembly of the mammalian Golgi is not understood but suggestions include that the process could be necessary for the correct division of the Golgi into the two daughter cells by the mitotic spindle during cell division [345] or that the Golgi disassembly might release proteins that are important for chromosome segregation or cytokinesis. Importantly and in contrast to mammalian Golgi, *Drosophila* Golgi stacks are not connected by a ribbon [183] and they do not fragment or disassemble [346]. But we know that Dragon exhibits dual localisation to the Golgi and the centrosome (section 5.2.2), and that the Golgi is associated with microtubules and the centrosome [184,345]. Initial pilot experiments of *in vitro* binding assay

failed to indicate direct protein interaction of CtBP with Dragon or Sas6 (data not shown). Could therefore CtBP function be part of a signalling pathway linking the Golgi and the centrosome or cilia for centriole biogenesis or cilia absorption; for the progress of the cell into mitosis; or the correct division of the Golgi into the two daughter cells during cell division? These speculations also go hand in hand with the finding that the centrosomal Dragon signal increases in interphase and adjusts to the levels of its interacting partner Sas6 thereafter (Figure 5-2). Additionally, the mammalian homologue CtBP is targeted by Pak1 kinase [347], which is required for mitotic entry [348]; and the function of CtBP in mitotic entry could be conserved in *Drosophila*. Dragon's specific function at the Golgi was not the focus in this study and further studies need to be performed to understand its potential role in secretion and signalling pathways.

5.3.3 Physical interaction of Dragon and Sas6

My findings demonstrate that Dragon and Sas6 interact directly with each other *in vitro* (section 5.2.4.1). It is Sas6 fragments that contain the C-terminal region of the coiled-coil domain that interact with Dragon *in vitro* (schematic in Figure 5-6). Significantly, this region was not described previously. On the other hand, the N-terminal head domain of Sas6 form the cartwheel hub of centrioles, and the N-terminal regions of the coiled-coil domains of two Sas6 molecules dimerise and form a spoke of the centriole cartwheel. The most truncated protein fragments of Sas6 that still interact strongly with Dragon are the segments aa351-472 and Sas6 aa1-462 (Figure 5-6, Figure 5-7). The latter is potentially truncated by the majority of the predicted unstructured C-terminal domain of Sas6. Figure 5-9 suggests that the predicted coiled-coil domain ends around aa450 and a closer analysis of the homology alignment of Sas6 from multiple species in Figure 5-8 shows a two amino acids insertion (QK: Glutamine and Lysine respectively) only in *Drosophila* at aa449-450 and could potentially be the site of transition from coiled-coil to unstructured protein sequence. The homology alignment of Sas6 (Figure 5-8) shows conserved regions but it does not identify a specifically and highly conserved domain in the C-terminal region of the coiled-coil domain.

The structural features of *Drosophila* Dragon protein are uncharacterised. It has a predicted C-terminal coiled-coil domain (aa191-318, Figure 5-12) that interacts directly with Sas6 *in vitro* (Figure 5-10, Figure 5-11). Significantly, the C-terminal third fragment of Dragon (aa244-339), which is smaller and misses the N-terminal part of the coiled-coil domain, interacts only weakly with Sas6. This suggests a specific interaction of the whole coiled-coil domain of Dragon with Sas6. This notion is supported by the alignment studies of *Drosophila* Dragon aa190-320 with other species, which confirms that the coiled-coil domain is highly conserved between species (Figure 5-13). On the other hand, sequences N- and C-terminal to the coiled-coil region show almost no conserved residues, apart from a short 12 amino acid stretch in the N-terminus (aa5-16 in *Drosophila*, not shown). Thus, the coiled-coil domain is likely to play an important role that is conserved throughout species. The C-terminus of Dragon interacts with Sas6, making it likely that a C-terminally tagged Dragon is less efficient at interacting with Sas6, highlighting the importance of the accessibility of Dragon's C-terminally coiled-coil domain (section 5.2.4.3).

That Dragon interacts with C-terminal Sas6 suggests that it localises to the ends of the centriole cartwheel spokes. Potential functions could be stabilising the cartwheel endings; aiding and guiding Sas6 self-assembly abilities as a distance spacer between Sas6 cartwheel spokes; determining the 9-fold symmetry of the centriole; or supporting the transition zone between the cartwheel and microtubules. The specificity of Dragon interaction and co-localisation with Sas6 is intriguing as Dragon was not observed in other purifications of centriole duplication proteins. Preliminary attempts were made in collaboration with Dr. Gang Dong (Vienna) to address the stoichiometry of the Dragon and Sas6 interaction with the potential to purify an affinity complex for crystallisation trials. However the expression of Dragon resulted in low purification yields, and increasing concentrations led to aggregate formation. On the other hand, a smaller fragment of Dragon (aa172-339) proved unstable and degraded during purification. In summary, when Sas6 and Dragon are co-expressed, these problems of Dragon degradation and aggregation have not allowed to date for the measurement of exact binding affinities. Thus, it was not possible to

advance further structural examination of Dragon or its interaction with Sas6. Further studies will be required to precisely characterise Dragon's structure and function at the centrosome.

A region of potential Dragon self-interaction was found in the Dragon C-terminal third (aa244-339) that overlaps with the region that interacts directly with Sas6 (section 5.2.4.4, Figure 5-10, Figure 5-15). The potential of competition between Dragon oligomerisation and its interaction with Sas6 presents regulatory possibilities that should be studied further.

Protein phosphorylation plays a critical role in centriole duplication. Hennies *et al.* highlight that GoRab protein has many predicted phosphorylation sites (Figure 5-27A) [202], but Dragon has potentially many fold more possibilities of potential phosphorylation (Figure 5-27B). Remarkably there are clusters of predicted phosphorylation sites at Dragon aa79-94 and aa113-191, which are located directly upstream of the Sas6 binding site (aa191-318). This further fuels the idea that the phosphorylation of Dragon by an unknown kinase might be necessary for its function at the centrosome or Golgi. To gain a better understanding of Dragon's function at both the centrosome and Golgi, it will be important to identify and characterise other interacting proteins of Dragon and the phosphodependence of their interactions. Additionally, this might further our understanding of the microtubule nucleation functions of the centrosome and the Golgi, and a potential link between the two processes.

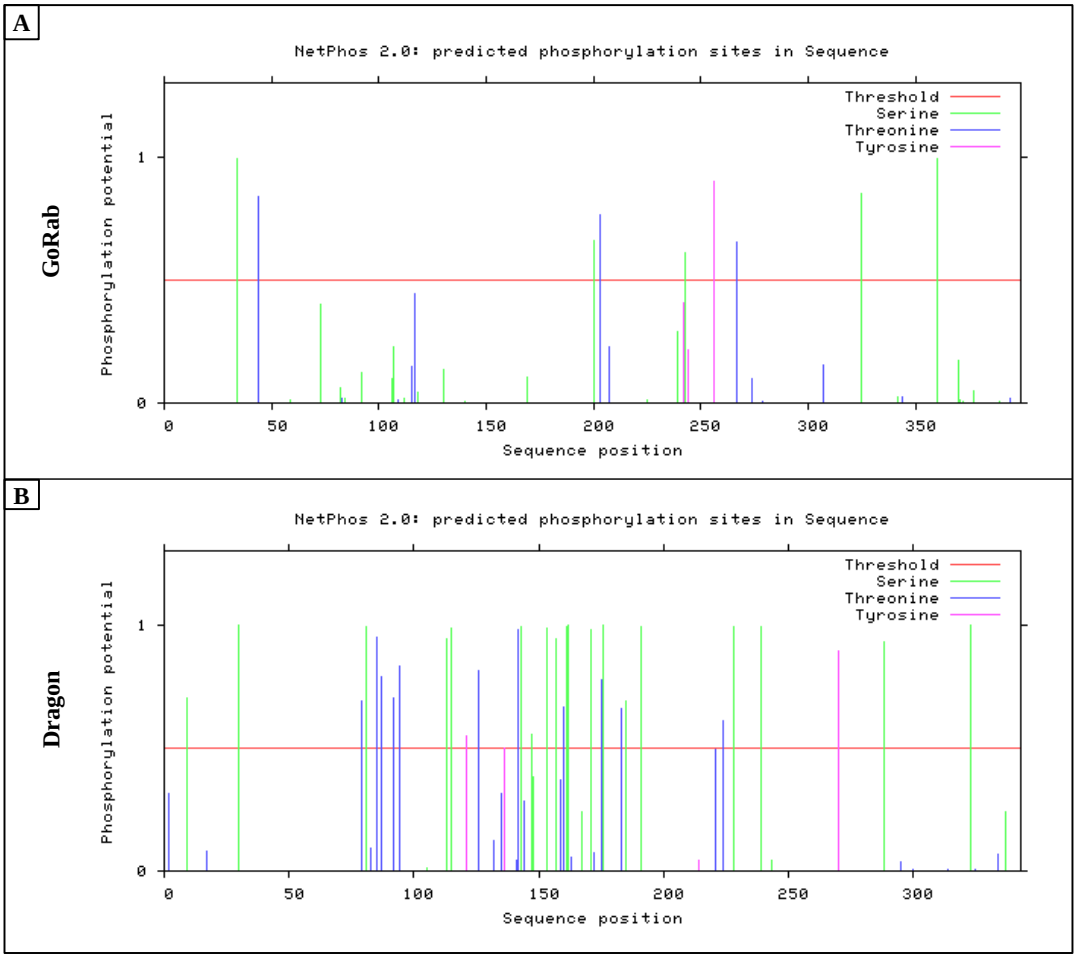

Figure 5-27 Predicted generic phosphorylation sites in the homologous GoRab (A) and Dragon (B). Analyses performed with NetPhos 2.0 Server [349] over the whole protein sequences of GoRab and Dragon. The sequence position of potential phosphorylation sites (in amino acids) are blotted against their phosphorylation potential (with 0 to 1 equalling 'unlikely' to 'very likely', and the threshold in red at 0.5). Pictured are predicted phosphorylation sites for Serine (green), Threonine (blue) and Tyrosine (pink). The closer the phosphorylation potential towards 1, the more 'very likely' is the predicted phosphorylation site a true phosphorylation site.

To study the cellular effect of loss of interaction between Dragon and Sas6 at the centrosome, I further analysed which smaller site in Dragon aa191-318 was essential for interaction with Sas6. A mutant that lacks the region aa260-286 cannot interact with Sas6 *in vitro* (section 5.2.5.1). This interaction motif (IM) could be the necessary site for direct protein-protein interaction between Dragon and Sas6 or it could function as a "spacer" within

Dragon that leads to a secondary structure formation of Dragon that allows for physical interaction with Sas6. If this “spacer” was deleted, as for the Dragon$^{\Delta IM}$ mutant, it could change the secondary structure of Dragon and consequently its physical and structural ability to bind Sas6. The Dragon$^{\Delta IM}$ mutant cannot rescue the loss of centrosomes after the depletion of endogenous Dragon (section 5.2.5.3). Whether the loss of centrosomes after loss of interaction between Dragon and Sas6 is directly due to failed co-recruitment of Dragon and Sas6 to the procentriole or a missing protein interaction at the centrosome itself requires further study by immune fluorescence and especially high resolution structured illumination microscopy. This will shed light on the dependency of the interaction of Dragon and Sas6 on recruitment and localisation of the two proteins to the centrosome. Both possibilities are likely and yet it is surprising that Dragon has not been described previously in screens for *Drosophila* centriole duplication proteins [131,288]. Therefore, it seems rather likely that Dragon supports centriole duplication structurally by interacting with the cartwheel protein Sas6.

5.3.4 The human homologue GoRab and centriole duplication

The human homologue of Dragon, GoRab, has been described in relation to the disease Gerodermia osteodysplastica but a centrosomal connection has not been published. But alignments of Dragon and GoRab from different species, including *Drosophila* and *Homo sapiens*, show that the C-terminal domain of *Drosophila* aa191-318 is highly conserved (Figure 5-13, Figure 5-24). The identification of the novel direct interaction of Sas6 and Dragon and its effects on centriole duplication when Dragon is depleted or cannot interact with Sas6 raises the question if this function is conserved in the human homologue GoRab (section 5.2.6). Two functional isoforms of GoRab are known, GoRab variant 1 and GoRab variant 3, which share the same amino acid sequence but variant 3 is truncated at the C-terminus (Figure 5-22). A closer analysis of the isoforms with the homology alignment reveals that GoRab variant 3 does not align to the full Dragon region that interacts with Sas6

(aa191-318); it only contains most of the N-terminal region downstream of Dragon-IM (aa260-286). On the other hand, GoRab variant 1 aligns along the whole *Drosophila* Dragon sequence. The study of these two GoRab isoforms and their direct interaction with HsSas6 *in vitro* shows that only GoRab variant 1 is able to directly interact with HsSas6. Thus, as observed in *Drosophila*, also the human homologous GoRab and HsSas6 interact directly *in vitro* and the highly conserved C-terminal domain is necessary to allow for this interaction. The conserved interaction between GoRab and HsSas6 raises the question of whether there is a conserved functional role in centriole duplication in human cell culture. Performed siRNA experiments on U2Os cells revealed that the depletion of GoRab protein does result in failure of centriole duplication (Figure 5-26). This is in line with loss of centrosomes observed after Dragon depletion in *Drosophila* cell culture and the failure of Dragon$^{\Delta IM}$ to rescue centriole duplication.

Together the data presented in this chapter indicated that the novel direct interaction of Dragon/GoRab with Sas6 has a significant function in centriole duplication. Dragon and Sas6 interact within their C-terminal protein domains and have potential functions for both centriole duplication and structure. The roles of Dragon at the Golgi are less certain and further research will be necessary to further understand the role and specific function of Dragon in vesicle trafficking.

Chapter 6

Final discussion

6 Final discussion

This thesis focuses how the core proteins of the centriole interact with each other as a network, with a specific focus on the structural and functional interaction of Sas6 with Ana2 and Sas6 with Dragon in the process of centriole duplication.

In Chapter 3 I studied the interactions of centriole duplication proteins identified by mass spectrometric analysis of protein complexes purified using affinity tagged centriole duplication proteins in cultured *Drosophila* cells (section 3.2.1). I also performed protein-protein binding assays *in vitro* to test for direct protein interactions (section 3.2.2) and studied direct protein interactions *in vivo* by yeast-2-hybrid assays (section 3.2.3). Together this allowed me to build a protein network of potentially interacting centriole duplication proteins in relation to their localisation within the five zones of the centrosome [24,30]. Each of these three methods can be strong and reliable but in my hands they have proven to be a guide for further studies rather than giving conclusive results.

In Chapter 4 I focused on the core centriole duplication proteins Ana2 and Sas6, which were identified as centriole duplication proteins in two genome wide dsRNAi screens in *D. melanogaster* cell culture [131,288]. Moreover Sas6 was shown to be a major component of the centriole cartwheel [63,69,74,75]. In summary, I show that Plk4 and Ana2 interact directly with each other but that neither shows direct interaction with Sas6 using *in vitro* binding assays (section 4.2.1). Similarly, Plk4 phosphorylates Ana2 but not Sas6 *in vitro* (section 4.2.1.1). Phospho-peptide mapping by mass spectrometry identified that the residues S318, S365, S370 and S373 in the conserved Ana2-STAN motif are phosphorylated by Plk4 (section 4.2.2). Importantly, an Ana2-4A mutant that cannot be phosphorylated by Plk4 leads to loss of centrosomes, which in turn can be rescued by the phospho-mimicking Ana2-4D mutant (section 4.2.3). This suggests an essential downstream event of Ana2 phosphorylation for

centriole duplication. *In vitro* and *in vivo* studies showed that Plk4-phosphorylation of Ana2 mediates the interaction of the centriole cartwheel protein Sas6 with Ana2 (section 4.2.4). Structurally, the Plk4-phosphorylated Ana2-C-terminus is sufficient for the interaction with Sas6 (section 4.2.4.1); and specifically the four Serine residues within the Ana2-STAN motif (S318, S365, S370, S373) need to be phosphorylated by Plk4 for the interaction of Sas6 with Ana2-C-terminus to occur (section 4.2.5). Accordingly, the non-phosphorylatable Ana2-4A mutant does not interact with Sas6 *in vitro*, whereas the phospho-mimicking Ana2-4D does (section 4.2.6). Further *in vitro* interaction studies revealed that the Plk4-phosphorylated Ana2-STAN motif alone is sufficient for interaction with Sas6 and that the Sas6 aa276-432 coiled-coil segment is efficient in binding Ana2 (section 4.2.8).

In Chapter 5 I report the identification and initial characterisation of a novel protein Dragon (CG33052) that associates with centrosomes and the Golgi. Dragon was identified by mass spectrometry analysis of Sas6-complexes purified from cultured *Drosophila* cells (section 6.2.1.1). Reciprocal purifications of Dragon from cultured *Drosophila* cells identified the centrosomal cartwheel protein Sas6 and subunits of the Golgi COPI protein in complex with Dragon (section 6.2.1.2 and section 6.2.1.3). Dragon is a novel protein that exhibits dual localisation at the *trans*-Golgi and the centrosome in *Drosophila* cell culture. Dragon co-localises with the cartwheel protein Sas6 at the centriole throughout its duplication cycle (section 6.2.2). *In vitro* binding assays confirmed that Dragon interacts directly with Sas6 (section 6.2.4). Specifically, the segment of Sas6 between aa351-462 interacts directly with the conserved Dragon C-terminal coiled-coil domain (aa191-318) within which the sequence between aa260-286 is necessary for interaction with Sas6. The human homologues of Dragon and Sas6, GoRab variant 1 and HsSas6 respectively, also interact directly *in vitro* (section 6.2.6.1). Depletion of Dragon/GoRab causes loss of centrosomes in *Drosophila* cell culture and human U2Os cells (section 6.2.3 and section 6.2.6.2 respectively). Moreover a Dragon$^{\Delta IM}$ mutant that does not interact with Sas6 *in vitro* or *in vivo* fails to rescue centriole duplication in *Drosophila* cell culture (section 6.2.5). Thus Dragon appears necessary for

centriole duplication. In contrast, the precise function of Dragon at the Golgi and potentially in secretory pathways is uncertain.

The relationship between Plk4, Ana2 and Sas6 and their role in procentriole formation was further characterised by examining loading dependencies *in vivo* using structured illumination microscopy to assess loading (expertise of Dr. Tzolovsky, RNAi by Dr. Dzhindzhev). These studies support the *in vitro* findings [296]. Together this establishes the loading dependencies of Ana2 and Sas6 and characterises their interaction in relation to their localisation at the centriole. In wild-type *Drosophila* cells, endogenous Sas6 and Ana2 localise to the mother and the daughter centriole as two independent dots throughout the cell cycle (the outer centriolar marker D-Plp allows mother and daughter centrioles to be distinguished; Figure 6-1). In interphase and prometaphase, Sas6 and Ana2 localise to the centre of the mother centriole and D-Plp ring, and to the daughter centriole which has yet to develop its D-Plp ring. The daughter centriole matures by recruiting D-Plp in a “horn” like pattern around the centriole and completes its ring structure by meta-/anaphase. This is followed by disengagement of the mother and daughter centriole in anaphase. In late ana-/telophase, each of the separated centrioles shows a new dot for Ana2 and Sas6 at the periphery of the mother D-Plp ring. This characterises the site of the nascent procentriole, which is already determined at telophase and not after cytokinesis in G_1, as previously believed.

Significantly, the depletion of Sas6 by RNAi does not have an effect on the above described centriole localisation of Ana2 in the majority of analysed *Drosophila* cells, with the majority of interphase cells exhibiting two dots of Ana2, of which one is in the centre and one on the periphery of the D-Plp ring, the mother centriole and the site of procentriole formation respectively (Figure 6-2). This suggests that Ana2 localises to the centriole independently of Sas6. Therefore, Ana2 maintenance at the mother centriole and Ana2 recruitment to the site of procentriole formation does not depend on Sas6. On the contrary, depletion of Ana2 or Plk4 by RNAi causes Sas6 to localise to a single dot at the mother centriole in the centre of the D-Plp ring. Localisation of Sas6 to a second dot at the periphery of the D-Plp ring and

therefore to the site of procentriole formation does not occur in the majority of Ana2 depleted interphase cells (Figure 6-3A). Thus individually depleting Ana2 or Plk4 does not allow for Sas6 to be recruited to the site of procentriole formation but they do not interfere with maintenance of Sas6 at the mother centriole. In other words, the loading of Sas6 and consequential the formation of the procentriole are dependent on Ana2. The lack of Sas6 recruitment could be due to the lack of Plk4 or Ana2 protein after their depletion thus preventing potential physical interactions between Sas6 and Ana2.

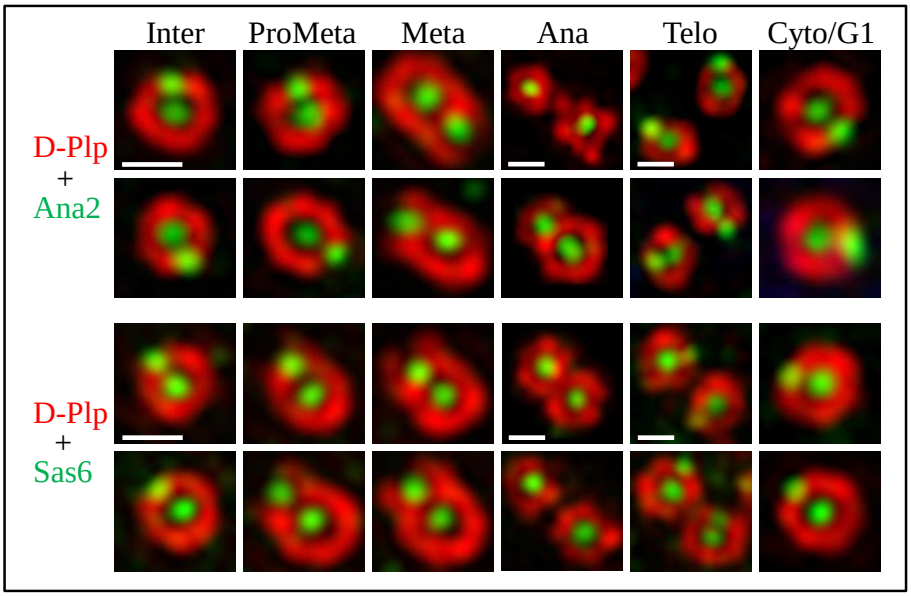

Figure 6-1 Localisation of endogenous Ana2 and Sas6 relative to D-Plp throughout the cell cycle. Structured illumination microscopy of endogenous Ana2, Sas6 and D-Plp throughout cell cycle stages in cultured *Drosophila* cells. Ana2 and Sas6 localise to the mother centriole at the centre of the D-Plp ring throughout the cell cycle. At mitotic entry, Ana2 and Sas6 localise as a second dot to the periphery of the D-Plp ring of the mother centriole, the site of procentriole formation. The second dot matures a D-Plp ring until meta-/anaphase, followed by disengagement of mother and daughter centriole. At late ana-/telophase, each of the two centrioles acquires a new dot of Ana2 and Sas6 at the new site of procentriole formation. Scale bar: 0.5µm. Images by Dr. Tzolovsky [296].

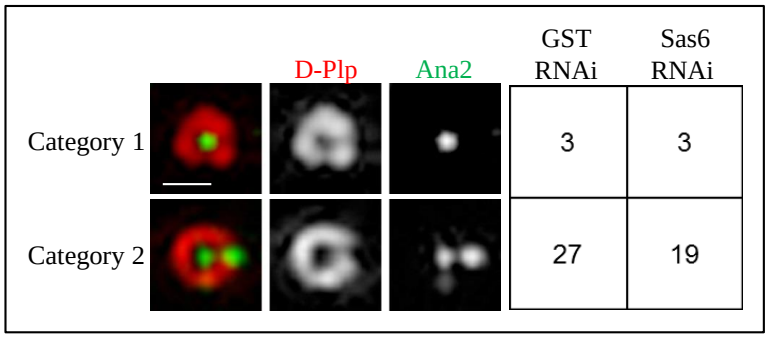

Figure 6-2 Ana2 localisation to the centriole is independent of Sas6. Structural illumination microscopy and categories of Ana2 in interphase *Drosophila* cells after Sas6 or control RNAi. Numbers on the right indicate how many centrioles were observed in each category. Ana2 localisation relative to the outer centriole marker D-Plp. The majority of cells exhibit a two dot localisation of Ana2 at the mother and procentriole. Scale bar: 0.5µm. Images by Dr. Tzolovsky [296].

Together with the described *in vitro* findings that Plk4 phosphorylates Ana2, to allow for Sas6 to interact with the phosphorylated Ana2 (section 4.2.4), this suggests that Sas6 localisation to the site of procentriole formation depends on the upstream event of Ana2 phosphorylation by Plk4. When endogenous Ana2 was depleted (by UTRs directed RNAi) from transgenic cells expressing Ana2-WT or Ana2-4A the majority of Ana2-WT cells exhibited the previously described double dot localisation of Ana2 and Sas6 to the centre and the periphery of the mother centriole D-Plp ring (Figure 6-1), whereas the majority of Ana2-4A expressing cells showed correct Ana2 localisation and the localisation of Sas6 is limited to the centre of the mother centrioles (Figure 6-4B). This resembles the findings of Sas6 localisation in wild-type *Drosophila* cells after RNAi of Ana2 or Plk4 (Figure 6-3). In summary, this confirms that the lack of Sas6 protein at the site of procentriole formation is due to the lack of Plk4-phosphorylated Ana2 and is therefore in line with the *in vitro* finding that Plk4-phosphorylation of Ana2 triggers its interaction with Sas6 (section 4.2.4). Additionally, this confirms that Ana2 is recruited to the centriole independently of its phosphorylation in the STAN motif by Plk4; and that Ana2 and Sas6 do not have to form a complex to allow for Ana2 recruitment to the centriole. This is in line with findings in human cells, where STIL and Sas6 have not been detected in a stable complex [117], nor using protein fragments in yeast-2-

hybrid assays [41]. This contrasts to Sas5 and Sas6 that form a complex and are recruited co-dependently to the procentriole in *C. elegans* [72].

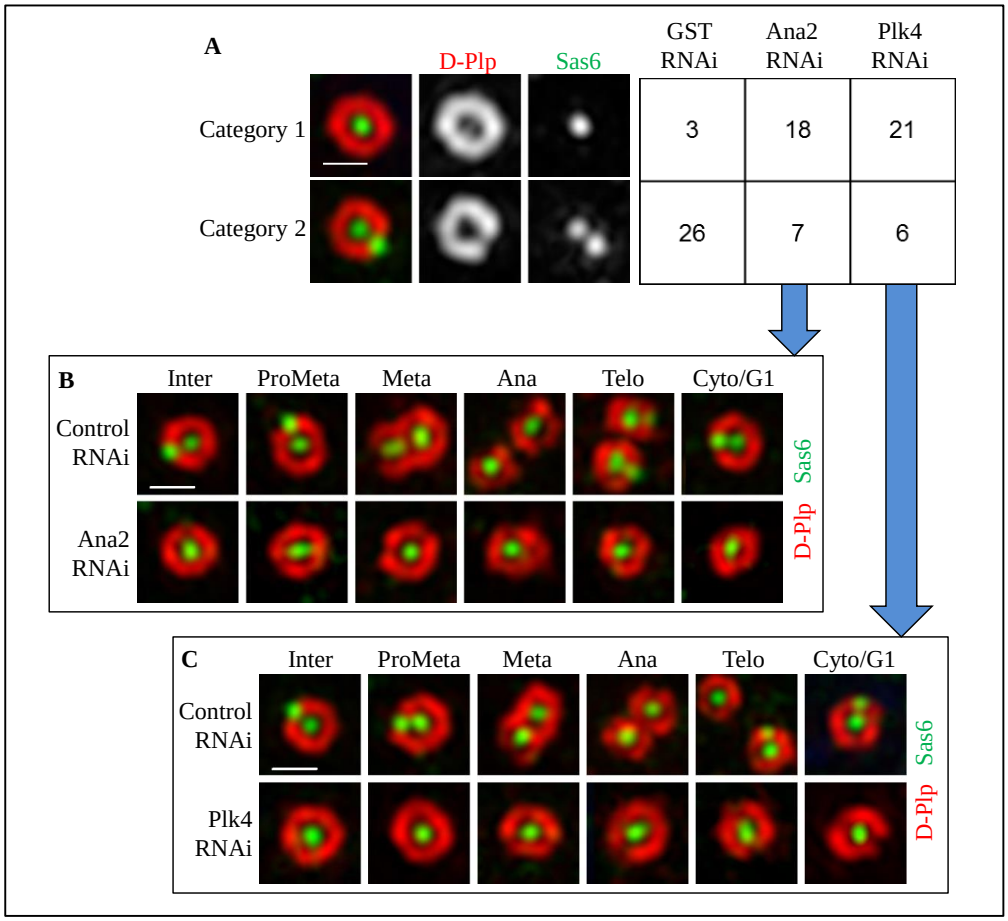

Figure 6-3 Ana2 and Plk4 are essential for centriolar loading of Sas6. Structured illumination microscopy of Sas6 and D-Plp in *Drosophila* cells after Ana2, Plk4 or control RNAi. Sas6 (green) localisation relative to the outer centriole marker D-Plp (red). (A) Categories of Sas6 localisation at the centriole as one or two dots and relative to number of times observed after Ana2, Plk4 or control RNAi. (B) Localisation of Sas6 relative to D-Plp throughout cell cycle stages after Ana2 or control RNAi. Cells depleted of endogenous Ana2 fail to load Sas6. (C) Localisation of Sas6 relative to D-Plp throughout cell cycle stages after Plk4 or control RNAi. Cells depleted of endogenous Plk4 or Ana2 fail to load Sas6. Scale bar: 0.5µm. Images by Dr. Tzolovsky [296].

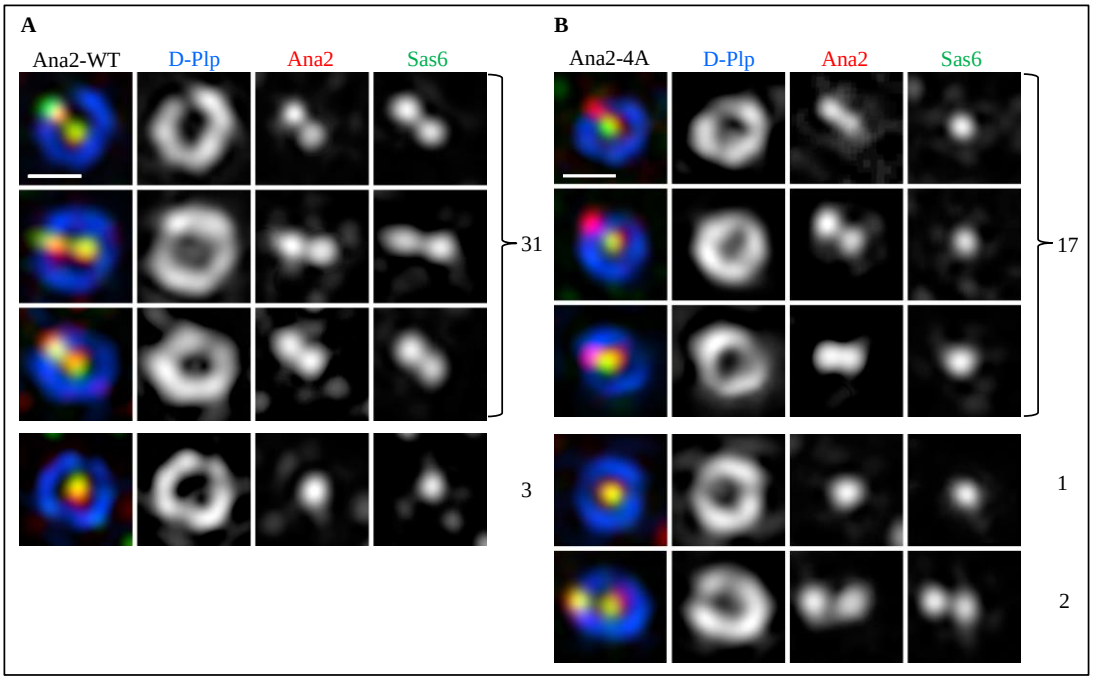

Figure 6-4 Plk4-mediated phosphorylation of S318, S365, S370 and S373 in the Ana2-STAN motif is essential for Sas6 recruitment to centrioles. Structured illumination microscopy of Ana2, Sas6 and D-Plp in interphase *Drosophila* cells expressing Ana2-WT (A) or Ana2-4A (B) after depletion of endogenous Ana2. Number of centrioles observed indicated on the right. (A) The majority of interphase cells expressing transgenic Ana2-WT exhibit co-localisation of Ana2 and Sas6 as two dots at the centre and the periphery of the D-Plp ring, the mother centriole and the site of procentriole initiation respectively. (B) The majority of interphase cells expressing transgenic Ana2-4A, a non-Plk4-phosphorylatable mutant at four Serine residues in the Ana2-STAN motif, which are essential for interaction with Sas6, has normal Ana2 localisation at the mother centriole and is recruited to the site of procentriole formation (two dots of Ana2, comparable to Ana2 localisation in Figure 6-4A). Sas6 only localises as one dot to the mother centriole and is not recruited to the site of procentriole formation. Scale bar: 0.5µm. Images by Dr. Tzolovsky [296].

It has also been suggested that the direct binding of Plk4 to STIL activates its kinase activity by promoting auto-phosphorylation of the activation loop in the kinase domain. This would provide a timely mechanism for Plk4 activity in centriole duplication because human Plk4 localises to the centriole throughout the cell cycle [26] whereas STIL only accumulates from late G_1-/early S-phase and is then degraded after anaphase onset in human cells [41,117,120]. Thus STIL could be a regulating protein for Plk4 and not only a target substrate. However,

human Plk4 becomes localised to a single site of procentriole formation at the beginning of S-phase [93–95]. So far, it is only known that depletion of STIL prevents this localisation of Plk4 to a single site [95] but the precise molecular basis of this remains unknown. How Ana2/STIL is recruited and how Plk4 is activated at a single site in the process are questions that remain to be answered. I have shown that Plk4-phosphorylation of the Ana2 STAN motif is necessary to allow Sas6 to bind to the single site and initiate procentriole formation. Similar findings have been made in human cells, where STIL S1108 and S1116 are phosphorylated by Plk4 and these phosphorylations are necessary for efficient targeting of STIL and Sas6 binding to the centriole [300]. We have shown that Ana2 does not require Plk4 phosphorylation at its STAN motif for centriole localisation. However in human cells, it has been suggested by Moyer *et al.* that the efficient targeting of STIL depends on STAN-phosphorylation by Plk4 but the actual interaction between the two proteins does not [300]. On the other hand Kratz *et al.* suggested that Plk4-phosphorylation of STIL is not mandatory for its interaction with Plk4 nor its localisation to the centriole but it is required to allow centriole duplication [123]. Significantly, the residue S1116, identified in human cells [123,300] corresponds to *Drosophila* S370 [95,296], thus confirming the conserved importance of this Plk4-phosphorylation site within the STIL/Ana2-STAN motif for centriole duplication. Interestingly, it is not the loss of the STAN motif but the loss of the central coiled-coil domain of STIL that strongly reduces its localisation to the centriole, as this was observed to be necessary for interaction with Plk4 [95]. A significant difference between *Drosophila* and human cells is seen in the recruitment of Sas6. Whereas Sas6 is recruited directly to the site of procentriole formation in *Drosophila*, the human Sas6 homologue is transiently recruited to the lumen of the mother centriole in early S-phase and then relocates to the outer wall in a process dependent upon Plk4 and STIL. This is followed by cartwheel and procentriole assembly [350], and then the cartwheel structure is lost again during daughter-to-mother centriole transitions in mitosis [120]. This occurs with the loss of centrosomal STIL by Cdk1, followed by loss of Sas6 from the centriole [120]; suggesting that dephosphorylation of STIL could potentially cause dissociation of Sas6 from the centriole.

It is remarkable that Sas6 does not interact with non-phosphorylated Ana2 at all. Therefore, phosphorylation of Ana2 must be tightly regulated, to guarantee its phosphorylation only occurs when recruitment of Sas6 and procentriole formation must be initiated. It is known from *C. elegans* that Sas5 and Sas6 are present as homodimers, before an unknown process allows them to form a complex [15,114,302,304]. However, the structural differences in the organisation of the core centriole and the arrangement of Sas6 in the two species may indicate a requirement for different regulatory steps. Further structural and molecular information on Ana2 and Sas6 complexes is needed, to fully understand the difference between their recruitment to the site of procentriole formation in *C. elegans* and *Drosophila* that reflect the structural character of tube and cartwheel respectively. How the structural arrangement of Ana2 and Sas6 correlates on a molecular basis with the phosphorylation state of Ana2 still needs to be answered.

Together, my results demonstrate that Ana2 and Plk4 are interacting proteins and that Plk4-mediated phosphorylation of Ana2 brings about the interaction of Sas6 with Ana2. Structured illumination microscopy by Dr. Tzolovsky additionally shows that Ana2 localises to the procentriole independently of its phosphorylation state by Plk4 and that Sas6 is recruited to the procentriole only when Ana2 is phosphorylated by Plk4. These results further our understanding of the molecular and functional processes during centriole duplication. For further directions, it is of utmost interest how Ana2 is recruited to the centriole, how it localises to a single site for procentriole formation and what regulates its timely recruitment. It is of interest to understand the structural complex between Ana2 and Sas6 as this will further our understanding of the instructural arrangements during procentriole formation.

The identification of the uncharacterised protein Dragon; its co-localisation with Sas6 at the centriole; and the finding that Dragon and Sas6 interact directly with each other is of particular interest. Dragon's human homologue GoRab localises to the *trans*-Golgi [202] and a null mutant has been identified in patients exhibiting gerodermia osteodysplastica [202].

Despite this knowledge the precise function of GoRab is unknown. Similarly, Dragon localises to the *trans*-Golgi and could function in signalling pathways as well as in connection with COPI transport vesicles because subunits of COPI were identified in complex with Dragon by mass spectrometry. However, the precise function of Dragon at the Golgi remains unknown. Dragon protein participates in centriole duplication because its depletion leads to loss of centrosomes. However, Dragon's precise molecular function at the centriole remains unknown. Additionally, I show that the conserved C-terminal coiled-coil domain of Dragon (aa191-318) interacts with the C-terminal part of the Sas6 coiled-coil domain (aa351-462). The latter region was not described in structural studies for the formation of the centriole cartwheel by Sas6. Thus Dragons could be important in the assembly of the procentriole or in the transition from the cartwheel assembly to interactions with microtubules. Dragon could structurally support the 9-fold symmetry of the centriole or directly connect proteins in the centriole assembly process. Importantly Dragon co-localises with Sas6 throughout the cell-cycle, suggesting it has a cartwheel related function or participates in another unidentified process that occurs with similar timing as Sas6 recruitment. From here onwards, studies of the interdependency between Dragon and Sas6 in their roles in centriole duplication and maturation need to be studied in greater detail. Additional structural knowledge of Dragon and Sas6 or their interacting regions in complex would lead to further understanding of the arrangement of these proteins at the centriole and what roles they might have on the cartwheel of the centriole as a whole in guaranty of 9-fold symmetry. Once these questions have been answered and we have more knowledge about the function of Dragon at the centriole, we can determine the relationship between the centriole and the Golgi mediated by Dragon or its isoforms. Additional studies of Dragon at *Drosophila* spermatocytes and the basal body of the sperm are needed to elucidate its function at these sites.

Appendix

Appendix

Appendix A: Mass spectrometry results from purifications of centriole duplication proteins from cultured *Drosophila* cells.

Tables show the full list of hits identified from the stated purification; indicating CG numbers, Mascot scores, Number of peptides (#pep), and the Full name of the protein if available. Tables are supplementary to Table 3-1 and Table 3-2.

A.1 Act5-PrA-Plk4 purification from *Drosophila* cells

CG #	Score	#pep	Full name
CG7186	3411	118	Plk4
CG9277	1532	55	beta-Tubulin at 56D
CG4264	1051	37	Heat shock protein cognate 4
CG3401	935	35	beta-Tubulin at 60D
CG1913	895	30	alpha-Tubulin at 84B

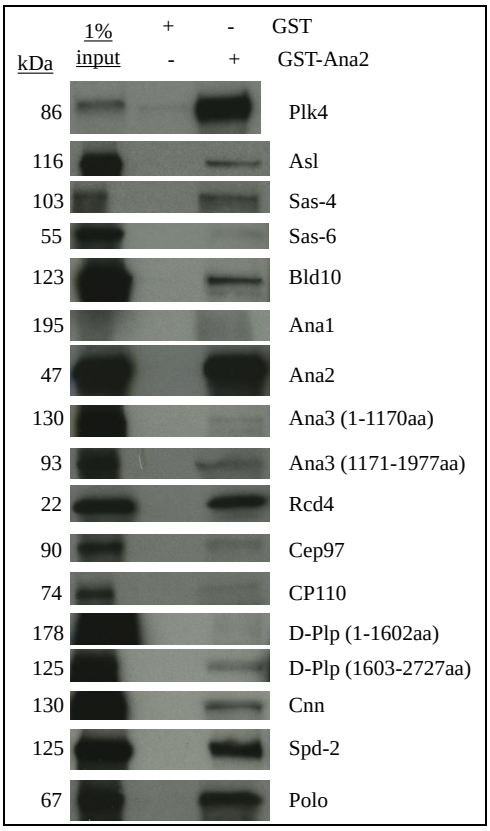
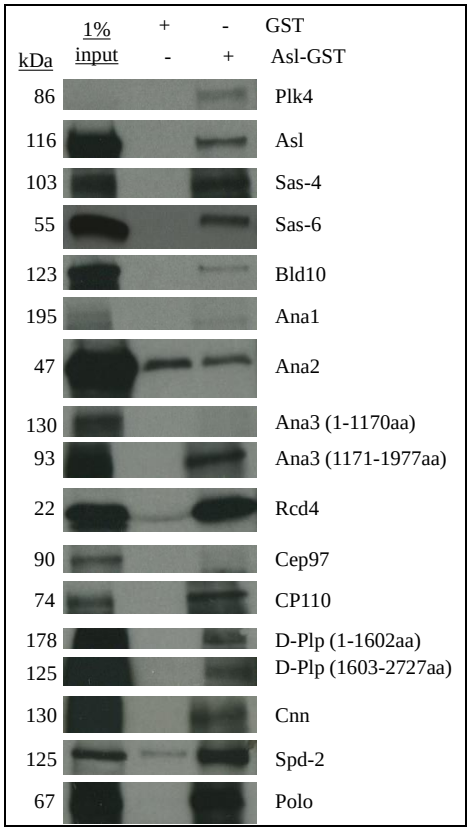
Appendix B: Autoradiograms of *in vitro* studies.

A-H showing autoradiographic signals from binding assays of ^{35}S-Methionine-labelled centriole duplication proteins with (A) GST-Ana2, (B) Asl-GST, (C) GST-Cep97, (D) GST-CP110 1/3, (E) GST-CP110 3/3, (F) MBP-Plk4, (G) GST-Rcd4, and (H) GST-Sas4 immobilised on resin; the according negative control (GST- or MBP-alone immobilised on resin; and 1% input of the ^{35}S-Methionine-labelled centriole duplication protein used in each binding assay. Autoradiographic signals were applied to categorise the analysed direct protein-protein interactions into weak, good, strong and no interaction in Table 3-3.

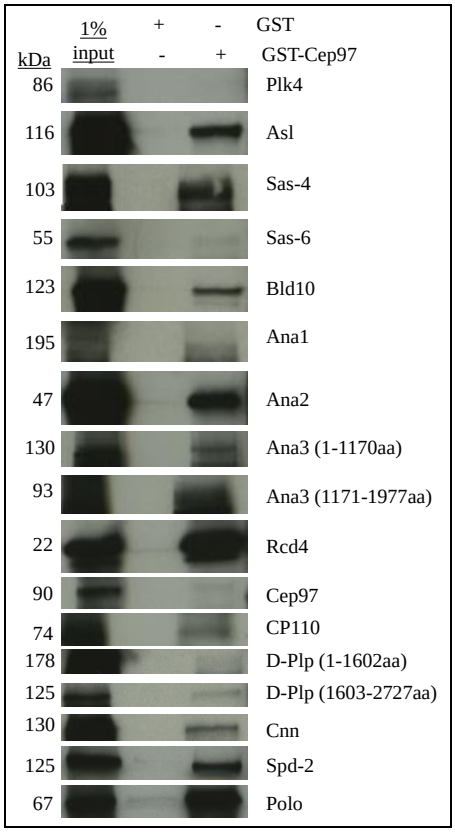
A) *In vitro* interaction with GST-Ana2



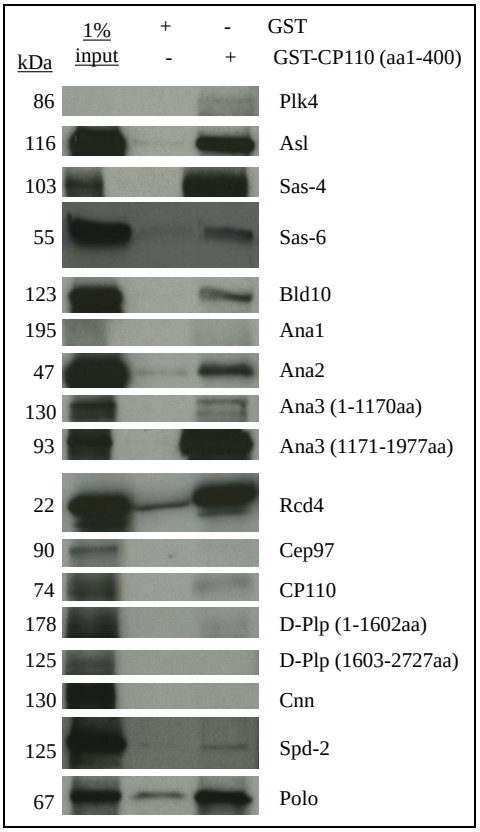
B) *In vitro* Interaction with Asl-GST



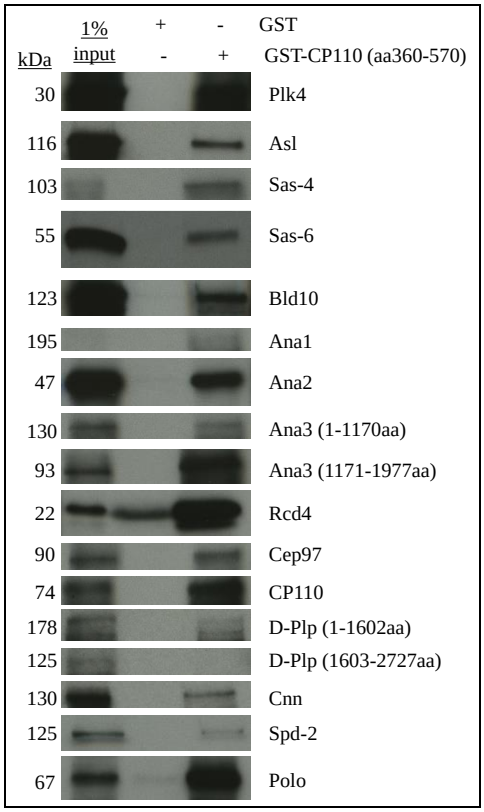
C) *In vitro* interaction with GST-Cep97



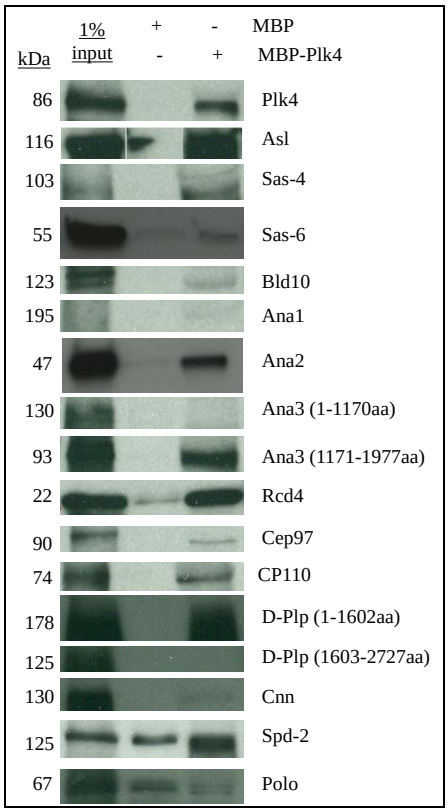
D) *In vitro* Interaction with GST-CP110 1/3



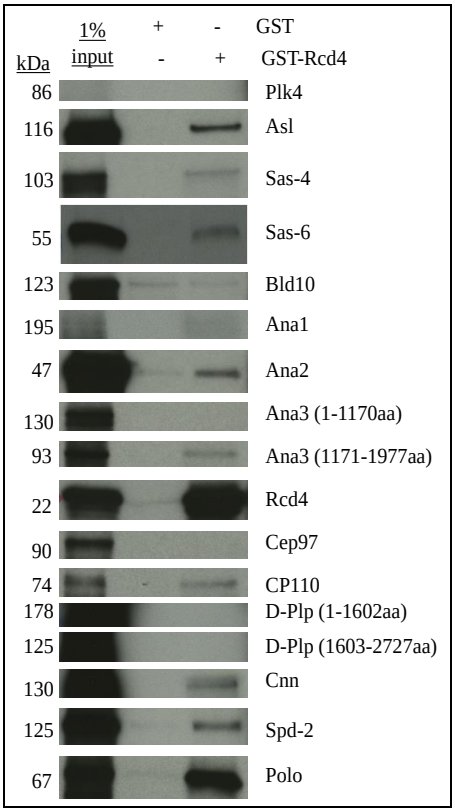
E) *In vitro* interaction with GST-CP110 2/3



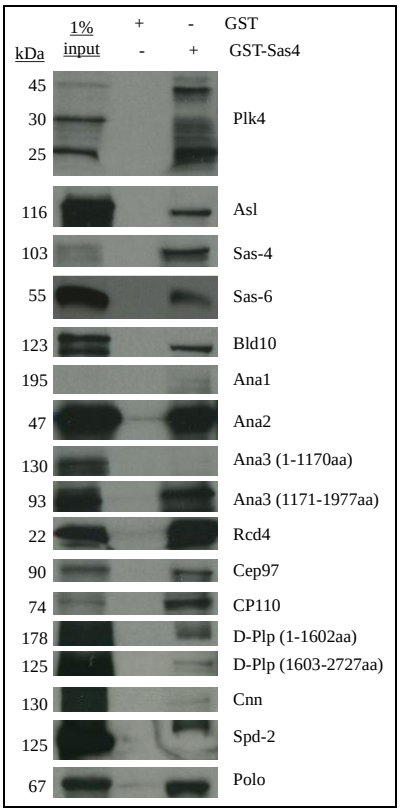
F) *In vitro* Interaction with MBP-Plk4



G) *In vitro* interaction with GST-Rcd4



H) *In vitro* Interaction with GST-Sas4



Appendix C: Mass spectrometry results from purifications of centriole duplication proteins from cultured *Drosophila* cells and syncytial *Drosophila* embryos.

Tables show the full list of hits identified from the stated purification; indicating CG numbers, Mascot scores, Number of peptides (#pep), and the Full name of the protein if available. Tables are supplementary to Table 5-1 and Table 5-2.

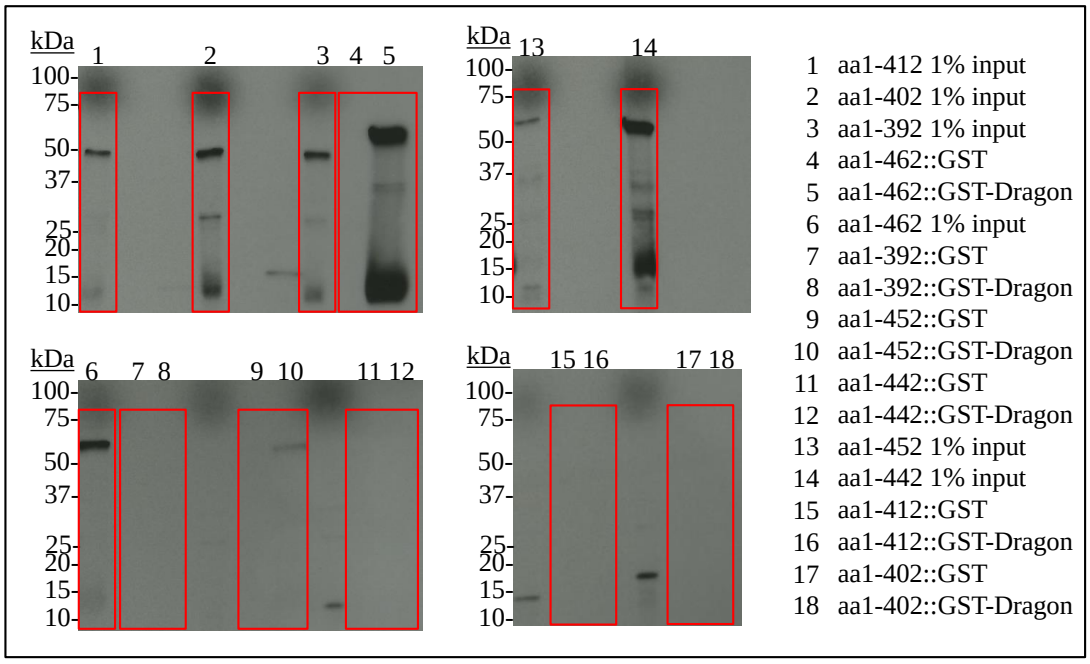
CG1554	28	1	RNA polymerase II 215kD subunit
CG10922	28	1	La autoantigen-like
CG11020	28	1	no mechanoreceptor potential C
CG15848	28	1	Sarcoplasmic calcium-binding protein 1
CG11471	28	1	Isoleucyl-tRNA synthetase
CG5252	28	1	Ranbp9
CG2522	27	1	GTP-binding protein
CG5183	27	1	KDEL receptor
CG4633	27	1	mitochondrial alanyl-tRNA synthetase
CG12499	27	1	CG12499
CG17510	27	1	Fis1
CG32146	27	1	dally-like
CG32683	27	1	CG32683
CG31175	27	1	Dystrophin
CG17870	26	1	14-3-3ζ
CG8749	26	1	small ribonucleoprotein particle U1 subunit 70K
CG7405	26	1	Cyclin H
CG17838	26	1	Syncrip
CG33233	26	1	CG33233
CG8793	26	1	lethal (3) 76BDm
CG4001	25	1	Phosphofructokinase
CG10859	25	1	CG10859
CG32016	25	1	eIF4E-Transporter
CG43063	25	1	CG43063
CG14816	23	1	Phosphoglycerate mutase 5
CG31116	23	2	Chloride channel-a
CG32210	23	1	Listerin E3 ubiquitin protein ligase 1
CG42327	23	1	CG42327
CG18176	21	1	deflated
CG1716	20	1	Set2

C.10 pUb-GFP-Dragon purification from syncytial *Drosophila* embryos

CG #	Score	#pep	Full name
CG33052	2764	50	CG33052
CG4264	1590	25	Heat shock protein cognate 4
CG8280	1028	15	Elongation factor 1α48D
CG15524	752	18	Spindle assembly abnormal 6 ortholog (C. elegans)
CG9277	731	17	β-Tubulin at 56D
CG9277	656	14	β-Tubulin at 56D
CG9359	506	11	β-Tubulin at 85D
CG4147	439	6	Heat shock 70-kDa protein cognate 3
CG8937	438	5	Heat shock protein cognate 1
CG8937	389	4	Heat shock protein cognate 1
CG18743	386	4	Heat-shock-protein-70Ab
CG2979	345	6	Yolk protein 2
CG4466	321	6	Heat shock protein 27
CG11129	315	7	Yolk protein 3
CG3401	308	9	β-Tubulin at 60D
CG1349	307	4	dj-1β
CG1873	300	6	Elongation factor 1α100E
CG7756	277	3	Heat shock protein cognate 2
CG4169	254	4	Ubiquinol-cytochrome c reductase core protein 2
CG10521	241	58	Netrin-B
CG4869	233	7	β-Tubulin at 97EF
CG7660	232	3	Peroxinectin-like
CG1913	215	5	α-Tubulin at 84B
CG17246	179	2	Succinate dehydrogenase A
CG9476	177	4	α-Tubulin at 85E
CG17291	173	3	Protein phosphatase 2A at 29B
CG3283	169	4	Succinate dehydrogenase B
CG5366	161	2	Cullin-associated and neddylation-dissociated 1
CG4916	141	3	maternal expression at 31B
CG8863	139	2	DnaJ-like-2
CG4183	133	2	Heat shock protein 26
CG33129	129	19	CG33129
CG4634	126	2	Nucleosome remodeling factor - 38kD
CG15825	121	1	fondue
CG10377	118	1	Heterogeneous nuclear ribonucleoprotein at 27C
CG12233	116	3	lethal (1) G0156
CG1263	114	1	Ribosomal protein L8
CG12306	113	1	polo
CG16944	110	6	stress-sensitive B
CG7349	104	2	Succinate dehydrogenase, subunit B (iron-sulfur)-like
CG6235	101	2	twins
CG14648	100	3	lost
CG1548	97	2	cathD
CG5371	94	2	Ribonucleoside diphosphate reductase large subunit
CG5499	88	2	Histone H2A variant
CG5261	87	2	midline uncoordinated
CG13422	87	1	GNBP-like 3
CG12262	83	1	CG12262
CG11181	80	1	cup
CG2985	80	4	Yolk protein 1
CG2168	77	1	Ribosomal protein S3A
CG8947	77	1	26-29kD-proteinase
CG11793	69	2	Superoxide dismutase
CG4916	69	2	maternal expression at 31B
CG1372	67	1	yolkless
CG15693	66	1	Ribosomal protein S20
CG8308	64	2	α-Tubulin at 67C
CG1683	64	1	Adenine nucleotide translocase 2
CG3203	64	1	Ribosomal protein L17
CG1242	59	1	Heat shock protein 83
CG1782	59	2	Ubiquitin activating enzyme 1
CG12244	58	2	licorne
CG7361	57	1	Rieske iron-sulfur protein

CG4193	56	1	deadhead
CG4863	56	1	Ribosomal protein L3
CG5504	53	1	lethal (2) tumorous imaginal discs
CG11276	53	1	Ribosomal protein S4
CG5502	52	1	Ribosomal protein L4
CG3024	52	1	Torsin
CG4651	51	1	Ribosomal protein L13
CG12052	50	1	longitudinals lacking
CG8415	50	1	Ribosomal protein S23
CG33456	50	2	muscle wasted
CG12369	49	12	Lachesin
CG6782	49	1	scheggia
CG5252	47	1	Ranbp9
CG9738	44	1	MAP kinase kinase 4
CG7977	44	1	Ribosomal protein L23A
CG13671	44	9	CG13671
CG1633	42	1	thioredoxin peroxidase 1
CG31884	41	1	thioredoxin-2
CG32164	40	1	CG32164
CG8905	37	1	Superoxide dismutase 2 (Mn)
CG5261	37	1	midline uncoordinated
CG4752	37	5	CG4752
CG31038	35	3	CG31038
CG2048	34	1	discs overgrown
CG4683	34	2	Testis EndoG-Like 4
CG10718	33	1	nebbish
CG9012	32	1	Clathrin heavy chain
CG6453	32	1	Glucosidase 2 β subunit
CG1821	31	1	Ribosomal protein L31
CG12163	31	1	CG12163
CG5263	30	1	smaug
CG2982	29	1	CG2982
CG9769	29	1	CG9769
CG7985	28	1	CG7985
CG33322	28	1	CG33322
CG32599	28	1	CG32599
CG42333	28	1	Synaptotagmin β
CG8246	27	1	Pox neuro
CG40478	27	1	Dual-specificity tyrosine phosphorylation-regulated kinase 3
CG14961	27	2	CG14961
CG10617	27	1	Synaptotagmin 12
CG8900	26	1	Ribosomal protein S18
CG2179	26	1	Xe7
CG16827	26	1	Integrin alphaPS4 subunit
CG31029	26	1	CG31029
CG12079	26	1	NADH dehydrogenase (ubiquinone) Fe-S protein 3
CG10594	25	2	spook
CG12164	25	1	CG12164
CG8907	25	2	CG8907
CG7413	24	1	Retinoblastoma-family protein
CG9809	24	1	spargel
CG8201	23	2	par-1
CG16983	22	1	skpA
CG5762	22	2	CG5762
CG2050	21	1	modulo
CG9537	21	2	Daxx-like protein
CG7369	21	1	CG7369
CG34434	21	1	CG34434
CG12055	20	1	Glyceraldehyde 3 phosphate dehydrogenase 1
CG9081	20	1	Cyp4s3
CG10021	19	1	brother of odd with entrails limited
CG9674	19	1	CG9674
CG1842	18	1	Dynein heavy chain at 89D
CG9159	18	2	Kruppel homolog 2
CG15744	18	1	CG15744
CG42346	18	1	CG42346
CG8817	17	1	lilliputian
CG30281	17	1	CG30281
CG7378	16	1	CG7378
CG12836	16	1	CG12836
CG3350	16	1	bigmax
CG17632	15	1	brown
CG11387	15	1	cut
CG11254	15	1	maelstrom
CG8322	15	1	ATP citrate lyase
CG6509	15	1	Discs large 5
CG11107	15	1	DHX15 ortholog
CG9168	15	1	CG9168
CG30484	15	1	CG30484
CG10375	14	1	CG10375

Appendix D



D.1 Original autoradiogram of four gels with indicated boxes that were cropped for Figure 5-12C. Numbers are explained in figure legend on the right. Domains of Sas6 in aa (amino acids); 1% input of ^{35}S-Methionine-labelled Sas6 fragment that was used for each binding assay; binding assays of ^{35}S-Methionine-labelled Sas6 fragment with GST-alone immobilised on resin (::GST) or GST-N-terminally tagged Dragon immobilised on resin (::GST-Dragon).
